**VCL**

**Content negotiation**

**Content negotiation Functions**

1. **accept.charset_lookup()**

   Selects the best match from a string in the format of an `Accept-Charset` header's value in the listed character sets, using the algorithm described in [RFC 7231](https://tools.ietf.org/html/rfc7231).

   This function takes the following parameters:
   1. a colon-separated list of character sets available for the resource,
   2. a fallback return value,
   3. a string representing an `Accept-Charset` header's value.

   **Format**

   ```
   STRING accept.charset_lookup(STRING requested_charsets, STRING default, STRING accept_header)
   ```

   **Examples**

   ```
   set bereq.http.Accept-Charset =
   accept.charset_lookup("iso-8859-5:iso-8859-2", "utf-8",
   req.http.Accept-Charset);
   ```

2. **accept.encoding_lookup()**

   Selects the best match from a string in the format of an `Accept-Encoding` header's value in the listed content encodings, using the algorithm described in 5.3.3 of [RFC 7231](https://tools.ietf.org/html/rfc7231).

   This function takes the following parameters:
   1. a colon-separated list of content encodings available for the resource,
   2. a fallback return value,
   3. a string representing an `Accept-Encoding` header's value.

   This function does not have special handling of `x-compress` or `x-gzip` values.

   **Format**

   ```
   STRING accept.encoding_lookup(STRING requested_content_encodings, STRING default, STRING accept_header)
   ```

   **Examples**

   ```
   set bereq.http.Accept-Encoding =
   accept.encoding_lookup("compress: gzip", "identity",
   req.http.Accept-Encoding);
   ```

3. **accept.language_filter_basic()**

   Similar to `accept.language_lookup()`, this function selects the best matches from a string in the format of an `Accept-Language` header's languages, using the algorithm described in [RFC 4647](https://tools.ietf.org/html/rfc4647), Section 3.3.1.

   This function takes the following parameters:
   1. a colon-separated list of languages available for the resource,
   2. a fallback return value,
   3. a string representing an `Accept-Language` header's value,
   4. the maximum number of matching languages to return.

   The matches are comma-separated.

   **Format**

   ```
   STRING accept.language_filter_basic(STRING requested_languages, STRING default, STRING accept_header, INTEGER nmatches)
   ```

   **Examples**

   ```
   ```
accept.language_lookup()

Selects the best match from a string in the format of an `Accept-Language` header's value in the listed languages, using the algorithm described in section 3.4.

This function takes the following parameters:

1. a colon-separated list of languages available for the resource,
2. a fallback return value,
3. a string representing an `Accept-Language` header's value.

This function conforms to RFC 4647.

Format

```
STRING
accept.language_lookup(STRING requested_languages, STRING default, STRING accept_header)
```

Examples

```
set bereq.http.Accept-Language =
accept.language_lookup("en:de:fr:nl", "en",
req.http.Accept-Language);
```

accept.media_lookup()

Selects the best match from a string in the format of an `Accept` header's value in the listed media types, using the algorithm described in section S.

This function takes the following parameters:

1. a colon-separated list of media types available for the resource,
2. a fallback return value,
3. a colon-separated list of media types, each corresponding to a media type pattern,
4. a string representing an `Accept` header's value.

The matching procedure is case insensitive, matched media types are returned verbatim as supplied to the matching function. Values of the `range_defaults` do not contain variables. Duplicate media types among the first three arguments are not allowed.

Format

```
STRING
accept.media_lookup(STRING requested_media_types, STRING default, STRING range_defaults, STRING accept_header)
```

Examples

```
# We wish `image/jpeg` to return `image/jpeg`.
# We wish `image/png` to return `image/png`.
# We wish `image/*` to return `image/tiff`.
# We wish `text/*` to return `text/html`.
# We wish `*/*` to return `text/plain`.
set beresp.http.media = accept.media_lookup("image/jpeg:image/png",
"text/plain",
"image/tiff:text/html",
req.http.Accept);
```

Cryptographic Notes

In Base64 decoding, the output theoretically could be in binary but is interpreted as a string. So if the binary output contains "\0" then it could be invalid.

The time based One-Time Password algorithm initializes the HMAC using the key and appropriate hash type. Then it hashes the message `(<time now in seconds since UNIX epoch> / <interval>) + <offset>` as a 64bit unsigned integer (little endian) and Base64 encodes the result.

Examples

One-Time Password Validation (Token Authentication)

Use this to validate tokens with a URL format like the following:
Example implementations for token generation in various languages can be found in GitHub.

```vcl
1
sub vcl_recv {
2
/* make sure there is a token */
3
if (req.url !~ "[?&]token=(\[^&\]+)"") {
4
token = error 403;
5 }
6
if (re.group.1 != digest.time_hmac_sha256("RemFzdGx5IFRva2VuIFRlc3Q=", 60, 0) &&
7
re.group.1 != digest.time_hmac_sha256("RemFzdGx5IFRva2VuIFRlc3Q=", 60, -1)) {
8
token = error 403;
9 }
10 #FASTLY recv ...
11 }
```

Signature
```
1 set resp.http.x-data-sig = digest.hmac_sha256("secretkey", resp.http.x-data);
```

Base64 decoding
A snippet like this in `vcl_error` would set the response body to the value of the request header field named `x-parrot` after Base64-decode.
```
1 synthetic digest.base64_decode(req.http.x-parrot);
```

However, if the Base64-decoded string contains a NUL byte (0x00), then that byte and any bytes following it will not be included in the response you intend to send a synthetic response that contains binary data. There is currently no way to send a synthetic response containing a NUL byte.

Cryptographic Functions

### digest.awsv4_hmac()
Returns an AWSv4 message authentication code based on the supplied `key` and `string`. This function automatically prepends "AWS4" in `key` (the first function parameter) as required by the protocol. This function does not support binary data for its `key` or `string` parameters.

**Format**
```
STRING
    digest.awsv4_hmac(STRING key, STRING date_stamp, STRING region, STRING service, STRING string)
```

**Examples**
```
1 declare local var.signature STRING;
2 set var.signature = digest.awsv4_hmac("wJalrXUtnFEMI/K7MDENG+bPxRfiCYEXAMPLEKEY",
3   "20120215",
4   "us-east-1",
5   "iam",
6   "hello");
```

### digest.base64_decode()
Returns the Base64 decoding of the input string, as specified by [RFC 4648](https://tools.ietf.org/html/rfc4648).

**Format**
```
STRING
    digest.base64_decode(STRING input)
```

**Examples**
```
1 declare local var.base64_decoded STRING;
2 set var.base64_decoded = digest.base64_decode("zprOsc67z47PgiDOv8+Bzq/Pg86xz4TOtQ==");
```

```
# var.base64_decoded is now "Καλώς ορίσατε"
```

### digest.base64()
Returns the Base64 encoding of the input string, as specified by [RFC 4648](https://tools.ietf.org/html/rfc4648).

**Format**
```
STRING
    digest.base64(STRING input)
```

**Examples**
```
1 declare local var.base64_encoded STRING;
2 set var.base64_encoded = digest.base64("zprOsc67z47PgiDOv8+Bzq/Pg86xz4TOtQ==");
```

```
# var.base64_encoded is now "zprOsc67z47PgiDOv8+Bzq/Pg86xz4TOtQ=="
```
```plaintext
STRING

digest.base64(STRING input)

Examples
1 declare local var.base64_encoded STRING;
2 set var.base64_encoded = digest.base64("Καλώς ορίσατε");
3 # var.base64_encoded is now "zprOsc67z47PgiD0v8-Bzq_Pg86xz4ToT0=="

digest.base64url_decode()

Returns the Base64 decoding with URL and filename safe alphabet decoding of the input string, as specified by RFC 4648.

Format
STRING
digest.base64url_decode(STRING input)

Examples
1 declare local var.base64url_decoded STRING;
2 set var.base64url_decoded = digest.base64url_decode("zprOsc67z47PgiD0v8-Bzq_Pg86xz4ToT0==");
3 # var.base64url_decoded is now "Καλώς ορίσατε"

digest.base64url_nopad_decode()

Returns the Base64 decoding with URL and filename safe alphabet decoding of the input string, as specified by RFC 4648, without padding

Format
STRING
digest.base64url_nopad_decode(STRING input)

Examples
1 declare local var.base64url_nopad_decoded STRING;
2 set var.base64url_nopad_decoded = digest.base64url_nopad_decode("zprOsc67z47PgiD0v8-Bzq_Pg86xz4ToT0");
3 # var.base64url_nopad_decoded is now "Καλώς ορίσατε"

digest.base64url_nopad()

Returns the Base64 encoding with URL and filename safe alphabet encoding of the input string, as specified by RFC 4648, without padding

Format
STRING
digest.base64url_nopad(STRING input)

Examples
1 declare local var.base64url_nopad_encoded STRING;
2 set var.base64url_nopad_encoded = digest.base64url_nopad("Καλώς ορίσατε");
3 # var.base64url_nopad_encoded is now "zprOsc67z47PgiD0v8-Bzq_Pg86xz4ToT0"

digest.base64url()

Returns the Base64 encoding with URL and filename safe alphabet of the input string, as specified by RFC 4648.

Format
STRING
digest.base64url(STRING input)

Examples
1 declare local var.base64url_encoded STRING;
2 set var.base64url_encoded = digest.base64url("Καλώς ορίσατε");
3 # var.base64url_encoded is now "zprOsc67z47PgiD0v8-Bzq_Pg86xz4ToT0=="

digest.hash_crc32()

Calculates the 32-bit Cyclic Redundancy Checksum with reversed bit ordering of a string, like that used by bzip2. Returns a hex-encoded string, e.g. 181989fc instead of fc891918.

Format

https://docs.fastly.com/vcl/aio
**STRING**
digest.hash_crc32(STRING input)

**Examples**

1 declare local var crc32 STRING;
2 set var.crc32 = digest.hash_crc32("123456789");
3 # var.crc32 is now "181989fc"

```
```

**digest.hash_crc32b()**

Calculates the 32-bit Cyclic Redundancy Checksum of a string, as specified by [ISO/IEC 13239:2002](https://docs.fastly.com/vcl/aio/) and section 8.1.1.6.2 of ITU-T recommendations. Ethernet (IEEE 802.3), V.42, FDDI, gzip, zip, and PNG. Returns a hex-encoded string in byte-reversed order, e.g. `2639f4cb` instead of `cbf42639`.

**Format**

**STRING**
digest.hash_crc32b(STRING input)

**Examples**

1 declare local var crc32b STRING;
2 set var.crc32b = digest.hash_crc32b("123456789");
3 # var.crc32b is now "2639f4cb"

```
```

**digest.hash_md5()**

Use the MD5 hash. Returns a hex-encoded string.

**Format**

**STRING**
digest.hash_md5(STRING input)

**Examples**

1 declare local var hash_md5 STRING;
2 set var.hash_md5 = digest.hash_md5("123456789");
3 # var.hash_md5 is now "25f9e794323b453885f5181f1b624d0b"

```
```

**digest.hash_sha1()**

Use the SHA-1 hash. Returns a hex-encoded string.

**Format**

**STRING**
digest.hash_sha1(STRING input)

**Examples**

1 declare local var hash_sha1 STRING;
2 set var.hash_sha1 = digest.hash_sha1("123456789");
3 # var.hash_sha1 is now "f7c3bc1d808e04732ad7f679965ccc34ca7ae3441"

```
```

**digest.hash_sha224()**

Use the SHA-224 hash. Returns a hex-encoded string.

**Format**

**STRING**
digest.hash_sha224(STRING input)

**Examples**

1 declare local var hash_sha224 STRING;
2 set var.hash_sha224 = digest.hash_sha224("123456789");
3 # var.hash_sha224 is now "9b3e61bf29f17c75572e2e1e7809a4513d07c8a18152acf34521"

```
```

**digest.hash_sha256()**

Use the SHA-256 hash. Returns a hex-encoded string.

**Format**

**STRING**
digest.hash_sha256(STRING input)

**Examples**

1 declare local var hash_sha256 STRING;
2 set var.hash_sha256 = digest.hash_sha256("123456789");
3 # var.hash_sha256 is now "9b3e61bf29f17c75572e2e1e7809a4513d07c8a18152acf34521"

```
```
STRING

digest.hash_sha256(STRING input)

Examples
1 declare local var.hash_sha256 STRING;
2 set var.hash_sha256 = digest.hash_sha256("123456789");
3 # var.hash_sha256 is now "15e2b0d3c33891eb07f1e609ec419428c20e320ce9465fbc83312448eb225"

igest.hash_sha384()
Use the SHA-384 hash. Returns a hex-encoded string.

Format
STRING
digest.hash_sha384(STRING input)

Examples
1 declare local var.hash_sha384 STRING;
2 set var.hash_sha384 = digest.hash_sha384("123456789");
3 # var.hash_sha384 is now "eb455d56d2c1a69de64e83201f3393d45f3fa31d6842f21af92d2fe469c499da5e3179847334a18479c8d1dedealbe3"

igest.hash_sha512()
Use the SHA-512 hash. Returns a hex-encoded string.

Format
STRING
digest.hash_sha512(STRING input)

Examples
1 declare local var.hash_sha512 STRING;
2 set var.hash_sha512 = digest.hash_sha512("123456789");
3 # var.hash_sha512 is now "d9e6762dd1c8eaf6d61b3c6192fc48d4d65f1176d0e29169bc24e713f274ad27fcd5811b313d681f7e55ec02d73d4918ffe85"

igest.hmac_md5_base64()
Hash-based message authentication code using MD5. Returns a Base64-encoded string.

Format
STRING
digest.hmac_md5_base64(STRING key, STRING input)

Examples
1 declare local var.hmac_md5_base64 STRING;
2 set var.hmac_md5_base64 = digest.hmac_md5_base64("key", "input");
3 # var.hmac_md5_base64 is now "cZ/HW66QBNnoQqSxW4KMBg=="

igest.hmac_md5()
Hash-based message authentication code using MD5. Returns a hex-encoded string prepended with 0x.

Format
STRING
digest.hmac_md5(STRING key, STRING input)

Examples
1 declare local var.hmac_md5 STRING;
2 set var.hmac_md5 = digest.hmac_md5("key", "input");
3 # var.hmac_md5 is now "0x719fc75bae9004d9e842a4b150b828c86"

igest.hmac_sha1_base64()
Hash-based message authentication code using SHA-1. Returns a Base64-encoded string.

Format
STRING
digest.hmac_sha1_base64(STRING key, STRING input)
Examples
1. declare local var.hmac_sha1_base64 STRING;
2. set var.hmac_sha1_base64 = digest.hmac_sha1_base64("key", "input");
3. # var.hmac_sha1_base64 is now "HR07V82z0KxXrnozmatcr9unyKf=

**digest.hmac_sha1()**

Hash-based message authentication code using SHA-1. Returns a hex-encoded string prepended with 0x.

**Format**

```
STRING
digest.hmac_sha1(STRING key, STRING input)
```

Examples
1. declare local var.hmac_sha1 STRING;
2. set var.hmac_sha1 = digest.hmac_sha1("key", "input");
3. # var.hmac_sha1 is now "0x8513bb355076cce2ae5eb9f399ab5cafdba7c8a2"

**digest.hmac_sha256_base64()**

Hash-based message authentication code using SHA-256. Returns a Base64-encoded string.

**Format**

```
STRING
digest.hmac_sha256_base64(STRING key, STRING input)
```

Examples
1. declare local var.hmac_sha256_base64 STRING;
2. set var.hmac_sha256_base64 = digest.hmac_sha256_base64("key", "input");
3. # var.hmac_sha256_base64 is now "ngiewTr4gaisInpzbD58SQ6jtK/KDF+D3/Y502g6cuM="

**digest.hmac_sha256()**

Hash-based message authentication code using SHA-256. Returns a hex-encoded string prepended with 0x.

**Format**

```
STRING
digest.hmac_sha256(STRING key, STRING input)
```

Examples
1. declare local var.hmac_sha256 STRING;
2. set var.hmac_sha256 = digest.hmac_sha256("key", "input");
3. # var.hmac_sha256 is now "0x9e089ec13af881a8ac227a736c3e7c490ea3b4afca0c5f83df6393b683a72e3"

**digest.hmac_sha512_base64()**

Hash-based message authentication code using SHA-512. Returns a Base64-encoded string.

**Format**

```
STRING
digest.hmac_sha512_base64(STRING key, STRING input)
```

Examples
1. declare local var.hmac_sha512_base64 STRING;
2. set var.hmac_sha512_base64 = digest.hmac_sha512_base64("key", "input");
3. # var.hmac_sha512_base64 is now "A613yBfzJmnMzzjayRXU5VoWgzb0S5Q6jtK/KDF+D3/Y502g6cuM=

**digest.hmac_sha512()**

Hash-based message authentication code using SHA-512. Returns a hex-encoded string prepended with 0x.

**Format**

```
STRING
digest.hmac_sha512(STRING key, STRING input)
```

Examples
1. declare local var.hmac_sha512 STRING;
2. set var.hmac_sha512 = digest.hmac_sha512("key", "input");
3. # var.hmac_sha512 is now "A613yBfzJmnMzzjayRXU5VoWgzb0S5Q6jtK/KDF+D3/Y502g6cuM=

https://docs.fastly.com/vcl/aio
declare local var.hmac_sha512 STRING;
set var.hmac_sha512 = digest.hmac_sha512("key", "input");
# var.hmac_sha512 is now "0x803ad77c81ff32659ecf38d9c915d4e55a16833b1ca685979a9df521a05235970b90043c3da402dad365ed39ac05af4e4c64ff95"

```plaintext
digest.rsa_verify()
```

A boolean function that returns true if the RSA signature of `payload` using `public_key` matches `digest`. The `hash_method` parameter specifies how the `payload` is digested. It can be `sha256`, `sha384`, `sha512`, or `default` (default is equivalent to `sha256`). The `STRING_LIST` parameter in the `payload/digest` parameter specifies the payload and digest. The `base64_method` parameter is optional. It can be `standard`, `url`, `url_nopad`, or `base64` (equivalent to `url_nopad`).

Format

```plaintext
BOOL digest.rsa_verify(ID hash_method, STRING_LIST public_key, STRING_LIST payload, STRING_LIST digest [, ID base64_method ])
```

Examples

```plaintext
1 if (digest.rsa_verify(sha256, 
"-----BEGIN PUBLIC KEY-----
aabbccddIieEffggHHhEXAMPLEPUBLICKEY
"-----END PUBLIC KEY-----"), req.http.payload, req.http.digest, url_nopad)) {
2 set req.http.verified = "Verified";
3 } else {
4 set req.http.verified = "Not Verified";
5 }
6 error 980;
```

```plaintext
digest.secure_is_equal()
```

A boolean function that returns true if `s1` and `s2` are equal. Comparison time varies on the length of `s1` and `s2` but not the contents of `s1` and `length`, the comparison is done in constant time to defend against timing attacks.

Format

```plaintext
BOOL digest.secure_is_equal(STRING_LIST s1, STRING_LIST s2)
```

Examples

```plaintext
1 if (!table.lookup(user2hashedpass, req.http.User) && digest.secure_is_equal(req.http.HashedPass, table.lookup(user2hashedpass))
2 error 401 "Unauthorized";
3 }
```

```plaintext
digest.time_hmac_md5()
```

Returns a time-based one-time password using MD5 based upon the current time. The `key` parameter is a Base64-encoded key. The `interval` parameter specifies the lifetime of the token and must be non-negative. The `offset` parameter provides a means for mitigating clock skew.

Format

```plaintext
STRING digest.time_hmac_md5(STRING key, INTEGER interval, INTEGER offset)
```

Examples

```plaintext
1 set req.http.otp-md5 = digest.time_hmac_md5(digest.base64("secret"), 60, 10);
```

```plaintext
digest.time_hmac_sha1()
```

Returns a time-based one-time password using SHA-1 based upon the current time. The `key` parameter is a Base64-encoded key. The `interval` parameter specifies the lifetime of the token in seconds and must be non-negative. The `offset` parameter provides a means for mitigating clock skew.

Format

```plaintext
STRING digest.time_hmac_sha1(STRING key, INTEGER interval, INTEGER offset)
```

Examples

```plaintext
1 set req.http.otp-sha1 = digest.time_hmac_sha1(digest.base64("secret"), 60, 10);
```

```plaintext
digest.time_hmac_sha256()
```

Returns a time-based one-time password with SHA-256 based upon the current time. The `key` parameter is a Base64-encoded key. The `interval` parameter specifies the lifetime of the token and must be non-negative. The `offset` parameter provides a means for mitigating clock skew.
### Date and time

#### Date and time Functions

**parse_time_delta()**

Parses a string representing a time delta and returns an integer number of seconds. This function supports the specifiers "d" and "D" for days, "m" and "M" for minutes, and "s" and "S" for seconds. The function parses individual deltas like "15m" and "7d". Strings like "10d11h3m2s" of invalid input, the function returns -1.

**Format**

```
INTEGER
parse_time_delta(STRING specifier)
```

**Examples**

```
set beresp.ttl = parse_time_delta(beresp.http.Edge-Control:cache-maxage);
```

**std.integer2time()**

Converts an integer, representing seconds since the UNIX Epoch, to a time variable.

If the time argument is invalid then this returns a time value which stringifies to: `datetime out of bounds`.

To convert a string, use **std.time()** instead.

**Format**

```
TIME
std.integer2time(INTEGER time)
```

**Examples**

```
declare local var.once TIME;
set var.once = std.integer2time(1136239445);
# var.once now represents "Mon, 02 Jan 2006 22:04:05 GMT"
```

**std.time()**

Converts a string to a time variable.

The following string formats are supported:

- `Mon, 02 Jan 2006 22:04:05 GMT`, **RFC 822** and **RFC 1123**
- `Monday, 02-Jan-06 22:04:05 GMT`, **RFC 850**
- `Mon Jan 22 04:05 2006`, **ANSI-C asctime()**
- `2006-01-02 22:04:05`, an **ISO 8601** subset
- `1136239445.00`, seconds since the **UNIX Epoch**
- `1136239445`, seconds since the **UNIX Epoch**
The only time zone supported is **GMT**.

If the string does not match one of those formats, then the fallback variable is returned instead. We recommend using a fallback that's near Fastly service.

**Format**

```
TIME
std.time(STRING s, TIME fallback)
```

**Examples**

```
1 declare local var.string TIME;
2 set var.string = std.time("Mon, 02 Jan 2006 22:04:05 GMT", std.integer2time(-1));
3 # var.string is now "Mon, 02 Jan 2006 22:04:05 GMT"
```

```
1 declare local var.integer TIME;
2 set var.integer = std.time("1136239445", std.integer2time(-1));
3 # var.integer is now "Mon, 02 Jan 2006 22:04:05 GMT"
```

```
1 declare local var.invalid TIME;
2 set var.invalid = std.time("Not a date", std.integer2time(-1));
3 # var.invalid is now "datetime out of bounds"
```

**strftime()**

Formats a time to a string. This uses [standard POSIX strftime formats](https://docs.fastly.com/vcl/aio).  

```
STRING
strftime(STRING format, TIME time)
```

**Examples**

```
# Concise format
set resp.http.now = strftime({"%Y-%m-%d %H:%M"}, now);
# resp.http.now is now e.g. 2006-01-02 22:04
```

```
# RFC 5322 format
set resp.http.start = strftime({"%a, %d %b %Y %T %z"}, time.start);
# resp.http.start is now e.g. Mon, 02 Jan 2006 22:04:05 +0000
```

```
# ISO 8601 format
set resp.http.end = strftime({"%Y-%m-%dT%H:%M:%SZ"}, time.end);
# resp.http.end is now e.g. 2006-01-02T22:04:05Z
```

**time.add()**

Adds a relative time to a time.

```
TIME
time.add(TIME t1, TIME t2)
```

**Examples**

```
1 declare local var.one_day_later TIME;
2 set var.one_day_later = time.add(now, 1d);
3 # var.one_day_later is now the same time tomorrow
```

**time.hex_to_time()**

This specialized function takes a hexadecimal string value, divides by **divisor** and interprets the result as seconds since the [UNIX Epoch](https://docs.fastly.com/vcl/aio).  

```
TIME
time.hex_to_time(INTEGER divisor, STRING dividend)
```

★ TIP: Regular strings ("short strings") in VCL use `%xx` escapes (percent encoding) for special characters, which would conflict with the format. For the strftime examples, we use VCL "long strings" `{...}`, which do not use the `%xx` escapes. Alternatively, you could use
Examples

```vcl
1 declare local var.hextime TIME;
2 set var.hextime = time.hex_to_time(1, "43b9a355");
3 # var.hextime is now "Mon, 02 Jan 2006 22:04:05 GMT"
```

### time.is_after()

Returns true if \( t_1 \) is after \( t_2 \). (Normal timeflow and causality required.)

**Format**

```vcl
BOOL
time.is_after(TIME t1, TIME t2)
```

**Examples**

```vcl
1 if (time.is_after(time.add(now, 10m), now)) {
2   ...
3 }
```

### time.sub()

Subtracts a relative time from a time.

**Format**

```vcl
TIME
time.sub(TIME t1, TIME t2)
```

**Examples**

```vcl
1 declare local var.one_day_earlier TIME;
2 set var.one_day_earlier = time.sub(now, 1d);
3 # var.one_day_earlier is now the same time yesterday
```

### Date and time Variables

#### now.sec

Like the `now` variable, but in seconds since the UNIX Epoch.

**Type**

`STRING`

**Accessibility**

Readable From

All subroutines

#### now

The current time in RFC 1123 format (e.g., Mon, 02 Jan 2006 22:04:05 GMT).

**Type**

`TIME`

**Accessibility**

Readable From

All subroutines

#### time.elapsed.msec_frac

The time that has elapsed in milliseconds since the request started.

**Type**

`STRING`

**Accessibility**

Readable From

All subroutines

#### time.elapsed.msec

The time since the request start in milliseconds.
Type

STRING

Accessibility
Readable From
All subroutines

=time.elapsed.sec
The time since the request start in seconds.

Type

STRING

Accessibility
Readable From
All subroutines

=time.elapsed.usec_frac
The time the request started in microseconds since the last whole second.

Type

STRING

Accessibility
Readable From
All subroutines

=time.elapsed_usec
The time since the request start in microseconds.

Type

STRING

Accessibility
Readable From
All subroutines

=time.elapsed
The time since the request started. Also useful for strftime().

Type

RTIME

Accessibility
Readable From
All subroutines

=time.end.msec_frac
The time the request started in milliseconds since the last whole second.

Type

STRING

Accessibility
Readable From
All subroutines

=time.end.msec
The time the request ended in milliseconds since the UNIX Epoch.

Type

STRING

Accessibility
Readable From
• \texttt{vcl\_deliver}
• \texttt{vcl\_log}

\texttt{time.end.sec}

The time the request ended in seconds since the UNIX Epoch.

Type
\texttt{STRING}

Accessibility
Readable From
• \texttt{vcl\_deliver}
• \texttt{vcl\_log}

\texttt{time.end.usec\_frac}

The time the request started in microseconds since the last whole second.

Type
\texttt{STRING}

Accessibility
Readable From
• \texttt{vcl\_deliver}
• \texttt{vcl\_log}

\texttt{time.end.usec}

The time the request ended in microseconds since the UNIX Epoch.

Type
\texttt{STRING}

Accessibility
Readable From
• \texttt{vcl\_deliver}
• \texttt{vcl\_log}

\texttt{time.end}

The time the request ended, using RFC 1123 format (e.g., \texttt{Mon, 02 Jan 2006 22:04:05 GMT}). Also useful for \texttt{strftime(\)}. Also useful for

Type
\texttt{TIME}

Accessibility
Readable From
• \texttt{vcl\_deliver}
• \texttt{vcl\_log}

\texttt{time.start.msec\_frac}

The time the request started in milliseconds since the last whole second, after TLS termination.

Type
\texttt{STRING}

Accessibility
Readable From
All subroutines

\texttt{time.start.msec}

The time the request started in milliseconds since the UNIX Epoch, after TLS termination.

Type
STRING

Accessibility
Readable From
All subroutines

**time.start.sec**

The time the request started in seconds since the UNIX Epoch, after TLS termination.

Type
STRING

Accessibility
Readable From
All subroutines

**time.start.usec_frac**

The time the request started in microseconds since the last whole second, after TLS termination.

Type
STRING

Accessibility
Readable From
All subroutines

**time.start.usec**

The time the request started in microseconds since the UNIX Epoch, after TLS termination.

Type
STRING

Accessibility
Readable From
All subroutines

**time.start**

The time the request started, after TLS termination, using RFC 1123 format (e.g., Mon, 02 Jan 2006 22:04:05 GMT).

Type
TIME

Accessibility
Readable From
All subroutines

**time.to_first_byte**

The time interval since the request started up to the point before the vcl_deliver function ran. When used in a string context, an RTIME value formatted as a number in seconds with 3 decimal digits of precision. In `vcl_deliver` this interval will be very close to time.elapsed. In use between time.elapsed and time.to_first_byte will be the time that it took to send the response body.

Type
RTIME

Accessibility
Readable From

- vcl_deliver
- vcl_log

**Edge Side Includes (ESI)**

**req esi**

Whether or not to disable or enable ESI processing during this request. Using `set req.esi = false;` will disable ESI processing. The default
Type

BOOL

Accessibility

Readable From

- vcl_recv
- vcl_fetch
- vcl_deliver
- vcl_error

req.topurl

In an ESI subrequest, contains the URL of the top-level request.

Type

STRING

Accessibility

Readable From

All subroutines

Floating point classification

Floating point values are grouped into one of several classifications:

- **Finite** — math.is_finite()
  
  A value that is neither NaN nor an infinity.

- **Subnormal** — math.is_subnormal()
  
  The FLOAT type supports subnormals (also known as denormals).

- **NaN** — math.is_nan()
  
  The FLOAT type may express NaN (Not a Number). In general, arithmetic operations involving a NaN will produce NaN. NaN values are fastly.error variable.

  There is no literal syntax for assigning NaN, but a math.NAN constant is provided.

- **Normal** — math.is_normal()
  
  A value that is neither NaN, subnormal, an infinity nor a zero.

  Note that "normal" is not the exact opposite of "subnormal" because of the other possible non-subnormal values.

- **Infinite** — math.is_infinite()
  
  The FLOAT type may express IEEE 754 infinities. These are signed values. Infinities behave with special semantics for some operators

  There is no literal syntax for assigning infinities, but math.POS_INFINITY and math.NEG_INFINITY constants are provided.

- **Zero** — There are two kinds of zero: positive and negative. Both compare equal.

  No VCL function is provided to determine whether a floating point value is a zero. Because both positive and negative zero compare equal made simply by var.x == 0.

Floating point classification Functions

math.isFinite()

Determines whether a floating point value is finite. See floating point classifications for more information.

Format

BOOL

math.isFinite(FLOAT x)

math.isInfinite()

Determines whether a floating point value is an infinity. See floating point classifications for more information.

Format

BOOL

math.is_infinite(FLOAT x)
```plaintext
1 declare local var.f FLOAT;
2 3 set var.f = math.POS_INFINITY;
4 set var.f = 1; # -1 produces NaN
5 if (math.is_infinite(var.f)) {
6    log "infinity";
7 }
```

### math.is_nan()

Determines whether a floating point value is NaN (Not a Number). See [floating point classifications](https://docs.fastly.com/vcl/aio/) for more information.

#### Format

```plaintext
BOOL
math.is_nan(FLOAT x)
```

#### Examples

```plaintext
1 declare local var.f FLOAT;
2 3 set var.f = 1;
4 set var.f /= 0;
5 if (math.is_nan(var.f)) {
6    log "division by zero";
7 }
```

### math.is_normal()

Determines whether a floating point value is normal. See [floating point classifications](https://docs.fastly.com/vcl/aio/) for more information.

#### Format

```plaintext
BOOL
math.is_normal(FLOAT x)
```

#### Examples

```plaintext
1 # zeroes are not normals
2 if (!math.is_normal(0)) {
3    log "not a normal";
4 }
```

### math.is_subnormal()

Determines whether a floating point value is subnormal. See [floating point classifications](https://docs.fastly.com/vcl/aio/) for more information.

#### Format

```plaintext
BOOL
math.is_subnormal(FLOAT x)
```

#### Examples

```plaintext
1 declare local var.f FLOAT;
2 3 set var.f = math.FLOAT_MIN; # minimum finite value
4 if (!math.is_subnormal(var.f)) {
5    log "not subnormal";
6 }
7 set var.f /= 2;
8 if (math.is_subnormal(var.f)) {
9    log "subnormal";
10 }
```

### Geolocation

All geographic data presented through these variables is associated with a particular IP address. This address is automatically populated from other variables but may be overridden explicitly by setting `client.geo.ip_override`.

Geographic variables representing names are available in several encodings. Note in particular the '*.ascii' variables are lossy. These variables are removed and are normalized to lowercase spellings. These '*.ascii' variables can be used as a symbolic string in code (for example, to per- encode the city name). Due to their simplified content, however, they are generally inappropriate for presenting to users.

#### NOTE:
While Fastly exposes these geographic variables, we cannot guarantee their accuracy. The variables are based on available geographic data and intended to provide an approximate location of where requests might be coming from, rather than an exact location. The postal code associated with the most granular level of geographic data available.
Using geographic variables with shielding

If you have shielding enabled, you should set the following variable before using geographic variables:

```c
set client.geo.ip_override = req.http.Fastly-Client-IP;
```

Absent data

⚠️ WARNING: The geolocation data is updated periodically as IP allocations change and various amendments are made. Some variables current data at any given time.

For **STRING** types, the special value `?` is used to indicate absent data. These may be normalized to VCL empty strings using the `if()` ternary operator:

```c
1 log if (client.as.name == "?", client.as.name, "");
```

In general strings in VCL may be not set (see the VCL documentation for types). This never occurs for the geolocation variables.

Reserved IP address blocks

The IPv4 and IPv6 address spaces have several blocks reserved for special uses. These include private use networks (e.g., 192.168.0.0/16), address ranges reserved for documentation (e.g., 203.0.113.0/24 RFC 5737 TEST-NET-3).

Geographic data has no meaningful association for these ranges. The geolocation VCL variables present special values for these ranges ins

<table>

Geolocation Variables

.client.as.name

The name of the organization associated with client.as.number.

For example, fastly is the value given for IP addresses under AS-54113.

Type

STRING

Accessibility

Readable From

All subroutines
Autonomous system (AS) number.

The `INTEGER` type in VCL is **wide enough** to support the full range of 32-bit AS numbers.

Formatting these numbers to base 10 (e.g., by implicit conversion to a `STRING` type) will give an `asplain` representation of the number, which is wide enough to support the full range of 32-bit AS numbers.

**RFC 5396** introduces the `asdot+` format, which represents a 32-bit AS number as two 16-bit parts. The following VCL illustrates constructing a number:

```vcl
1 declare local var_hi INTEGER;
2 declare local var_lo INTEGER;
3 set var_hi = client.as.number;
4 set var_hi >>= 16;
5 set var_lo = client.as.number;
6 set var_lo &= 0xFFFF;
7 log client.as.number = "" var_hi "." var_lo;
```

**Examples**

The 32-bit AS number 65550 (reserved by **RFC 5398** for documentation use) is rendered as `1.14`.

Several ranges of AS numbers are reserved for various purposes. The following VCL fragment illustrates categorizing AS numbers into these ranges:

```vcl
1 declare local var_as_category STRING;
2 if (client.as.number < 0 || client.as.number > 0xFFFFFFFF) {
3 set var_as_category = "invalid";
4 } else if (client.as.number == 0) {
5 set var_as_category = "reserved"; # RFC 1930
6 } else if (client.as.number <= 23455) {
7 set var_as_category = "public";
8 } else if (client.as.number <= 23456) {
9 set var_as_category = "transition"; # RFC 6793
10 } else if (client.as.number <= 64534) {
11 set var_as_category = "public";
12 } else if (client.as.number <= 64495) {
13 set var_as_category = "reserved";
14 } else if (client.as.number <= 65511) {
15 set var_as_category = "documentation"; # RFC 5398
16 } else if (client.as.number <= 65534) {
17 set var_as_category = "private";
18 } else if (client.as.number <= 66553) {
19 set var_as_category = "reserved";
20 } else if (client.as.number <= 66551) {
21 set var_as_category = "documentation"; # RFC 4893, RFC 5398
22 } else if (client.as.number <= 131071) {
23 set var_as_category = "reserved";
24 } else if (client.as.number <= 4199999999) {
25 set var_as_category = "public";
26 } else if (client.as.number <= 4294967294) {
27 set var_as_category = "private"; # RFC 6996
28 } else if (client.as.number >= 4294967295) {
29 set var_as_category = "reserved";
30 } else {
31 set var_as_category = "unknown";
32 }
```

**Type**

`INTEGER`

**Accessibility**

Readable From

All subroutines

`client.geo.area_code`

The telephone area code associated with the IP address. These are only available for IP addresses in the United States.

**Type**

`INTEGER`

**Accessibility**

Readable From

All subroutines

`client.geo.city.ascii`

City or town name, encoded using ASCII encoding. Lowercase ASCII approximation of the `.utf8` string with diacritics removed.
Type  
**STRING**

Accessibility  
Readable From  
All subroutines  

확장 가능한 도메인 관리자 (client.geo.city.latin1)  
City or town name, encoded using Latin-1 encoding.

Type  
**STRING**

Accessibility  
Readable From  
All subroutines  

확장 가능한 도메인 관리자 (client.geo.city.utf8)  
City or town name, encoded using UTF-8 encoding.

Type  
**STRING**

Accessibility  
Readable From  
All subroutines  

확장 가능한 도메인 관리자 (client.geo.city)  
Alias of `client.geo.city.ascii`.

Type  
**STRING**

Accessibility  
Readable From  
All subroutines  

확장 가능한 도메인 관리자 (client.geo.conn_speed)  
Connection speed. These connection speeds imply different latencies, as well as throughput.

Possible values are: broadband, cable, dialup, mobile, oc12, oc3, t1, t3, satellite, wireless, xdsl.

See [OC rates](https://docs.fastly.com/vcl/aio/) and [T-carrier](https://docs.fastly.com/vcl/aio/) for background on OC- and T- connections.

Type  
**STRING**

Accessibility  
Readable From  
All subroutines  

확장 가능한 도메인 관리자 (client.geo.continent_code)  
Two-letter code representing the continent. Possible codes are:

<table>
<thead>
<tr>
<th>Code</th>
<th>Continent</th>
</tr>
</thead>
<tbody>
<tr>
<td>AP</td>
<td>Africa</td>
</tr>
<tr>
<td>AN</td>
<td>Antarctica</td>
</tr>
<tr>
<td>AS</td>
<td>Asia</td>
</tr>
<tr>
<td>EU</td>
<td>Europe</td>
</tr>
<tr>
<td>NA</td>
<td>North America</td>
</tr>
<tr>
<td>OC</td>
<td>Oceania</td>
</tr>
<tr>
<td>SA</td>
<td>South America</td>
</tr>
</tbody>
</table>
These continents are defined by UN M.49.

The continent code for the Caribbean countries is NA.

Note that EU refers to the continent name, not to the European Union. For example, IP addresses allocated to Norway and Switzerland (not part of the European Union) are presented with the continent code EU, meaning the Europe.

**Type**

**STRING**

**Accessibility**

Readable From

All subroutines

**client.geo.country_code**

A two-character ISO 3166-1 country code for the country associated with the IP address. The US country code is returned for IP addresses United States military bases.

These values include subdivisions that are assigned their own country codes in ISO 3166-1. For example, subdivisions NO-21 and NO-22 are also assigned their own country codes (e.g., SJ for Svalbard and the Jan Mayen Islands).

**Examples**

The following VCL fragment uses a two-letter country code to construct an emoji flag from its corresponding Unicode regional indicator symbol:

```
1   table unicode_ri {
2     "A": \u{1F1E6}, "B": \u{1F1E7}, "C": \u{1F1E8}, "D": \u{1F1E9},
3     "E": \u{1F1EA}, "F": \u{1F1EB}, "G": \u{1F1EC}, "H": \u{1F1ED},
4     "I": \u{1F1EE}, "J": \u{1F1EF}, "K": \u{1F1F0}, "L": \u{1F1F1},
5     "M": \u{1F1F2}, "N": \u{1F1F3}, "O": \u{1F1F4}, "P": \u{1F1F5},
6     "Q": \u{1F1F6}, "R": \u{1F1F7}, "S": \u{1F1F8}, "T": \u{1F1F9},
7     "U": \u{1F1FA}, "V": \u{1F1FB}, "W": \u{1F1FC}, "X": \u{1F1FD},
8     "Y": \u{1F1FE}, "Z": \u{1F1FF}
9   }
10  set resp.http.X-Flag = table.lookup(unicode_ri, substr(client.geo.country_code, 0, 1))
11     table.lookup(unicode_ri, substr(client.geo.country_code, 1, 1));
```

For example, the country code SE will produce 🇸🇪 (the Swedish flag).

**Type**

**STRING**

**Accessibility**

Readable From

All subroutines

**client.geo.country_code3**

A three-character ISO 3166-1 alpha-3 country code for the country associated with the IP address. The USA country code is returned for IP overseas United States military bases.

**Type**

**STRING**

**Accessibility**

Readable From

All subroutines

**client.geo.country_name.ascii**

Country name, encoded using ASCII encoding.

This field is a lowercase transliteration of the ISO 3166-1 English short name for a country.

**Examples**

For example, the English short name for FK is FALKLAND ISLANDS (MALVINAS) and so the corresponding value of client.geo.country_name is islands (malvinas) (e.g., converted to lowercase).
Readable From
All subroutines

(client.geo.country_name.latin1)
Country name, encoded using Latin-1 encoding.

Type
STRING

Accessibility
Readable From
All subroutines

(client.geo.country_name.utf8)
Country name, encoded using UTF-8 encoding.

This field is the ISO 3166-1 English short name for a country.

Type
STRING

Accessibility

All subroutines

(client.geo.country_name.ascii)
Alias of client.geo.country_name.latin1.

Type
STRING

Accessibility
Readable From
All subroutines

(client.geo.gmt_offset)
Time zone offset from coordinated universal time (UTC) for client.geo.city.

Values may be negative. Values are given as base-10 numbers of three or four digits in the form (-)HHMM or (-)HMM, where H is hours and -230 would be offset of minus two hours and thirty minutes from UTC.

This may be formatted to an ISO 8601 four-digit form (-)HHMM using VCL:

```
declare local var offset STRING;
set var.offset = regsub(client.geo.gmt_offset, "^(-)?([^$]*)\$", "\10\2");
```

The special value 0 is used to indicate absent data. The special value 9999 is used to indicate an invalid region.

Examples

Not all timezone offsets are on the hour. For example, in St. John’s, Newfoundland, client.geo.gmt_offset may be -230 or -330 (depend time). The following VCL fragment produces a value in units of hours:

```
1 declare local var.offset_by_hour FLOAT;
2 set var.offset_by_hour = regsub(client.geo.gmt_offset, "^(-)?([^$]*)\$", "\10\2");
3 set var.offset_by_hour /= 60; # minutes
4 set var.offset_by_hour += std.atoi(regsub(client.geo.gmt_offset, "..\$", "")); # truncate
```

Here, increments of 0.5 correspond to half hours. For example, an offset of 930 will produce a floating point value of 9.5.

Type
INTEGER

Accessibility
Readable From
All subroutines
Override the IP address for geolocation data. The default is to use geolocation data for `client.ip`.

It is possible to set `client.geo.ip_override` to an invalid IP address:

```
1 set client.geo.ip_override = "xxx";
```

in which case the various geolocation variables present values to indicate an invalid region. `STRING` variables are set to the empty string, `FLOAT` 999.0, and `INTEGER` variables are set to 0.

**Type**

IP

**Accessibility**

Readable From

All subroutines

---

### client.geo.latitude

Latitude, in units of degrees from the equator. Values range from -90 to +90 inclusive, with the exception of the special value 999.9 used to indicate an invalid region.

The latitude given is based on the WGS 84 coordinate reference system.

**Examples**

An example showing construction of a geo URI as specified by RFC 5870 in VCL:

```
1 declare local var.geouri STRING;
2 set var.geouri = "geo:" + client.geo.latitude + "," + client.geo.longitude;
```

This produces a URI of the form `geo:37.786971,-122.399677` (where WGS 84 is the default CRS).

Here's an example showing classification to the five main geographical zones in VCL (latitude values as of October 2018):

```
1 declare local var.zone STRING;
2 if (client.geo.latitude == 999.9) {
3 set var.zone = "";
4 } else if (client.geo.latitude >= 66.5) { # Arctic circle
5 set var.zone = "North frigid";
6 } else if (client.geo.latitude >= 23.5) { # Topic of Cancer
7 set var.zone = "North temperate";
8 } else if (client.geo.latitude <= -66.5) { # Antarctic Circle
9 set var.zone = "South frigid";
10 } else if (client.geo.latitude <= -23.5) { # Tropic of Capricorn
11 set var.zone = "South temperate";
12 } else {
13 set var.zone = "Torrid";
14 }
```

You can use VCL to convert to degrees, minutes and seconds:
1 declare local var.deg INTEGER;
2 declare local var.min INTEGER;
3 declare local var.sec FLOAT;

4 declare local var.angle FLOAT;
5 declare local var.whole FLOAT;
6 declare local var.fraction FLOAT;

7 declare local var.fraction FLOAT;
8
9 set var.angle = client.geo.latitude; # input
10 if (var.angle < 0.0) {
11    set var.angle = -1;
12 }  
13
14 set var.fraction = var.angle;
15 set var.whole = var.fraction;
16 set var.fraction %= 1.0;
17 set var.whole = var.fraction;
18 set var.deg = var.whole;  # truncated, integer by rounding
19
20 set var.fraction *= 60.0;
21 set var.whole = var.fraction;
22 set var.fraction %= 1.0;
23 set var.whole = var.fraction;
24 set var.min = var.whole;  # truncated, integer by rounding
25
26 set var.sec = var.fraction;
27 set var.sec %= 1.0;  # floating seconds
28
29 log client.geo.latitude + " = " + var.deg "° " + var.min "′ " + var.sec "″"
30 + if (client.geo.latitude < 0.0, "S", "N");

For example, a latitude of 59.926 produces 59° 55′ 33.600″ N. The ‘′ and ′ symbols are Unicode prime symbols, not quotes.

Type
FLOAT

Accessibility
Readable From
All subroutines

client.geo.longitude

Longitude, in units of degrees from the IERS Reference Meridian. Values range from -180 to +180 inclusive, with the exception of the special symbol ‘±’ to indicate absent data.

The longitude given is based on the WGS 84 coordinate reference system.

Type
FLOAT

Accessibility
Readable From
All subroutines

client.geo.metro_code

Metro code.

Metro codes represent designated market areas (DMAs) in the United States.

Type
INTEGER

Accessibility
Readable From
All subroutines

client.geo.postal_code

The postal code associated with the IP address. These are available for some IP addresses in Australia, Canada, France, Germany, Italy, Spain, Kingdom, and the United States. We return the first 3 characters for Canadian postal codes. We return the first 2-4 characters (outward code United Kingdom. For countries with alphanumeric postal codes, this field is a lowercase transliteration.

Type
STRING
**Accessibility**

**Readable From**

All subroutines

- **client.geo.region.ascii**

  ISO 3166-2 country subdivision code. For countries with multiple levels of subdivision (for example, nations within the United Kingdom), this specific subdivision.

  The special value `NO REGION` is given for countries that do not have ISO country subdivision codes. For example, `NO REGION` is given for Åland Islands (country code AX, illustrated below).

  These region values are the subdivision part only. For typical use, a subdivision is normally formatted with its associated country code. The example illustrates constructing an ISO 3166-2 two-part country and subdivision code from the respective variables:

  ```
  1 declare local var.code STRING;
  2 if (client.geo.country_code != "**") {
  3    set var.code = client.geo.country_code;
  4    if (client.geo.region != "NO REGION" && client.geo.region != "?"") {
  5      set var.code = var.code + "-" + client.geo.region;
  6    }
  7 }```

**Examples**

Here are some example values:

<table>
<thead>
<tr>
<th>var.code</th>
<th>Region Name</th>
<th>Country</th>
<th>ISO 3166-2 subdivision</th>
</tr>
</thead>
<tbody>
<tr>
<td>AX</td>
<td>Öödkarby</td>
<td>Åland Islands</td>
<td>(none)</td>
</tr>
<tr>
<td>DE-BE</td>
<td>Berlin</td>
<td>Germany</td>
<td>Land (State)</td>
</tr>
<tr>
<td>GB-BNH</td>
<td>Brighton and Hove</td>
<td>United Kingdom</td>
<td>Unitary authority</td>
</tr>
<tr>
<td>JP-13</td>
<td>東京都 (Tōkyō-to)</td>
<td>Japan</td>
<td>Prefecture</td>
</tr>
<tr>
<td>RU-MOW</td>
<td>Москва́ (Moscow)</td>
<td>Russian Federation</td>
<td>Federal city</td>
</tr>
<tr>
<td>SE-AB</td>
<td>Stockholms län</td>
<td>Sweden</td>
<td>Län (County)</td>
</tr>
<tr>
<td>US-CA</td>
<td>California</td>
<td>United States</td>
<td>State</td>
</tr>
</tbody>
</table>

Here, the region name is given for sake of reference only. The region name is not provided as a VCL variable.

**Type**

Math rounding
See rounding modes for details of the rounding modes provided by these functions and for an overview of example values.

Math rounding Functions

math.ceil()
Computes the smallest integer value greater than or equal to the given value. In other words, round x towards positive infinity.
For example, 2.2, 2.5, and 2.7 all ceil to 3.0.

Return Value
If x is math.NAN, a NaN will be returned.
If x is integral, ±0, x itself is returned.
If x is math.POS_INFINITY or math.NEG_INFINITY, an infinity of the same sign is returned.
Otherwise, the rounded value of x is returned.

Format
FLOAT
math.ceil(FLOAT x)

math.floor()
Computes the largest integer value less than or equal to the given value. In other words, round x towards negative infinity.
For example, 2.2, 2.5, and 2.7 all floor to 2.0.

Return Value
If x is math.NAN, a NaN will be returned.
If x is integral, ±0, x itself is returned.
If x is math.POS_INFINITY or math.NEG_INFINITY, an infinity of the same sign is returned.
Otherwise, the rounded value of x is returned.

Format
FLOAT
math.floor(FLOAT x)

math.round()
Rounds x to the nearest integer, with ties away from zero (commercial rounding).

Return Value
If x is math.NAN, a NaN will be returned.
If x is integral, ±0, x itself is returned.
If x is math.POS_INFINITY or math.NEG_INFINITY, an infinity of the same sign is returned.
Otherwise, the rounded value of x is returned.

Format
FLOAT
math.round(FLOAT x)

**math.roundeven()**

Rounds x to nearest, ties to even (bankers' rounding).

**Return value**

If x is `math.NAN`, a NaN will be returned.
If x is integral, ±0, x itself is returned.
If x is `math.POS_INFINITY` or `math.NEG_INFINITY`, an infinity of the same sign is returned.
Otherwise, the rounded value of x is returned.

**Format**

FLOAT
math.roundeven(FLOAT x)

**math.roundhalfdown()**

Rounds to nearest, ties towards negative infinity (half down).

**Return value**

If x is `math.NAN`, a NaN will be returned.
If x is integral, ±0, x itself is returned.
If x is `math.POS_INFINITY` or `math.NEG_INFINITY`, an infinity of the same sign is returned.
Otherwise, the rounded value of x is returned.

**Format**

FLOAT
math.roundhalfdown(FLOAT x)

**math.roundhalfup()**

Rounds to nearest, ties towards positive infinity (half up).

**Return value**

If x is `math.NAN`, a NaN will be returned.
If x is integral, ±0, x itself is returned.
If x is `math.POS_INFINITY` or `math.NEG_INFINITY`, an infinity of the same sign is returned.
Otherwise, the rounded value of x is returned.

**Format**

FLOAT
math.roundhalfup(FLOAT x)

**math.trunc()**

Truncates x to an integer value less than or equal in absolute value. In other words, rounds x towards zero. Negative values will be rounded down towards zero.

For example, 2.2, 2.5, and 2.7 all truncate to 2.0.
This is equivalent to formatting the number to base ten and removing all digits after the decimal point.

**Return value**

If x is `math.NAN`, a NaN will be returned.
If x is integral, ±0, x itself is returned.
If x is `math.POS_INFINITY` or `math.NEG_INFINITY`, an infinity of the same sign is returned.
Otherwise, the rounded value of x is returned.

**Format**

FLOAT
math.trunc(FLOAT x)
Math trigonometric
Math trigonometric Functions

math.acos()
Computes the principal value of the arc cosine of its argument \( x \).

Parameters
\( x \) - Floating point value. The value of \( x \) should be in the range -1 to 1 inclusive.

Return value
Upon successful completion, this function returns the arc cosine of \( x \) in the range 0 to \( \pi \) radians inclusive.

If \( x \) is \( \text{math.NAN} \), a NaN will be returned.
If \( x \) is +1, +0 will be returned.
If \( x \) is \( \text{math.POS_INFINITY} \) or \( \text{math.NEG_INFINITY} \), a domain error occurs and a NaN will be returned.

For finite values of \( x \) not in the range -1 to 1 inclusive, a domain error occurs and a NaN will be returned.

Errors
If the \( x \) argument is finite and is not in the range -1 to 1 inclusive, or is \( \text{math.POS_INFINITY} \) or \( \text{math.NEG_INFINITY} \), then \text{fastly.error} will be set to \text{EDOM}.

Format

\[
\text{FLOAT}
\text{math.acos(FLOAT} \ x)\]

Examples

```math
1 declare local var.fo FLOAT;
2 set var.fo = math.cos(1.1); // Returns math.NAN
4 if (fastly.error) {
6  set resp.http.acos-error = fastly.error; // Returns "EDOM"
7 }
```

math.acosh()
Computes the inverse hyperbolic cosine of its argument \( x \).

Parameters
\( x \) - Floating point value representing the area of a hyperbolic sector.

Return value
Upon successful completion, this function returns the inverse hyperbolic cosine of \( x \).

If \( x \) is \( \text{math.NAN} \), a NaN will be returned.
If \( x \) is +1, +0 will be returned.
If \( x \) is \( \text{math.POS_INFINITY} \), \( \text{math.POS_INFINITY} \) will be returned.
If \( x \) is \( \text{math.NEG_INFINITY} \), a domain error occurs and a NaN will be returned.

For finite values of \( x < 1 \), a domain error occurs and a NaN will be returned.

Errors
If the \( x \) argument is finite and less than +1.0, or is \( \text{math.NEG_INFINITY} \), then \text{fastly.error} will be set to \text{EDOM}.

Format

\[
\text{FLOAT}
\text{math.acosh(FLOAT} \ x)\]

Examples

```math
1 declare local var.fo FLOAT;
2 set var.fo = math.acosh(10);
```

math.asin()
Computes the principal value of the arc sine of the argument \( x \).
Parameters

$x$ - Floating point value. The value of $x$ should be in the range $\text{-1 to 1 inclusive.}$

Return value

Upon successful completion, this function returns the arc sine of $x$, in the range $\text{-math.PI_2 to math.PI_2 radians inclusive.}$

If $x$ is $\text{math.NAN}$, a NaN will be returned.

If $x$ is $x \leq 0$, $x$ will be returned.

If $x$ is $\text{math.POS_INFINITY}$ or $\text{math.NEG_INFINITY}$, or $\text{math.NEG_INFINITY}$, a NaN will be returned.

If $x$ is subnormal, a range error occurs and $x$ will be returned.

For finite values of $x$ not in the range -1 to 1 inclusive, a domain error occurs and a NaN will be returned.

Errors

- If the $x$ argument is finite and is not in the range -1 to 1 inclusive, or is $\text{math.POS_INFINITY}$ or $\text{math.NEG_INFINITY}$, then $\text{fastly.err}$ will be set to $\text{ERANGE}$.  
- If the $x$ argument is subnormal, then $\text{fastly.error}$ will be set to $\text{ERANGE}$.

Format

```c
FLOAT
math.asin(FLOAT x)
```

Examples

1 declare local var.fo FLOAT;
2 set var.fo = math.asin(1.0);

**math.asinh()**

Computes the inverse hyperbolic sine of its argument $x$.

Parameters

$x$ - Floating point value representing the area of a hyperbolic sector.

Return value

Upon successful completion, this function returns the inverse hyperbolic sine of $x$.

If $x$ is $\text{math.NAN}$, a NaN will be returned.

If $x$ is $x \leq 0$, or $\text{math.POS_INFINITY}$ or $\text{math.NEG_INFINITY}$, $x$ will be returned.

If $x$ is subnormal, a range error occurs and $x$ will be returned.

Errors

If the $x$ argument is subnormal, then $\text{fastly.error}$ will be set to $\text{ERANGE}$.

Format

```c
FLOAT
math.asinh(FLOAT x)
```

Examples

1 declare local var.fo FLOAT;
2 set var.fo = math.asinh(1);

**math.atan()**

Computes the principal value of the arc tangent of its argument $x$.

Parameters

$x$ - Floating point value.

Return value

Upon successful completion, this function returns the arc tangent of $x$ in the range $\text{-math.PI_2 to math.PI_2 radians inclusive.}$

If $x$ is $\text{math.NAN}$, a NaN will be returned.

If $x$ is $x \leq 0$, $x$ will be returned.

If $x$ is $\text{math.POS_INFINITY}$ or $\text{math.NEG_INFINITY}$, $x$ will be returned.

If $x$ is subnormal, a range error occurs and $x$ will be returned.

Errors

If the $x$ argument is subnormal, then $\text{fastly.error}$ will be set to $\text{ERANGE}$.

Format

```c
FLOAT
math.atan(FLOAT x)
```

Examples

1 declare local var.fo FLOAT;
2 set var.fo = math.atan(1.0);
If x is subnormal, a range error occurs and x will be returned.

**Errors**

If the x argument is subnormal, then `fastly.error` will be set to `ERANGE`.

**Format**

```c
FLOAT
math.atan(FLOAT x)
```

**Examples**

```
1 declare local var.fo FLOAT;
2 set var.fo = math.atan(1);
```

### math.atan2()

Computes the principal value of the arc tangent of y/x, using the signs of both arguments to determine the quadrant of the Return Value.

**Parameters**

- y - Floating point value.
- x - Floating point value.

**Return value**

Upon successful completion, this function returns the arc tangent of y/x in the range -\( \text{math.PI} \) to \( \text{math.PI} \) radians inclusive. If y is ±0 and x is < 0, ±\( \text{math.PI} \) will be returned. If y is ±0 and x is > 0, ±0 will be returned. If y is < 0 and x is ±0, -\( \text{math.PI/2} \) will be returned. If x is 0, a pole error will not occur. If either x or y is `math.NAN`, a NaN will be returned. If y is ±0 and x is ±0, ±0 will be returned. For finite values of ±y > 0, if x is `math.NEG_INFINITY`, ±\( \text{math.PI} \) will be returned. For finite values of ±y > 0, if x is `math.POS_INFINITY`, ±0 will be returned. For finite values of x, if y is `math.POS_INFINITY` or `math.NEG_INFINITY`, ±\( \text{math.PI/2} \) will be returned. If y is `math.POS_INFINITY` or `math.NEG_INFINITY` and x is `math.NEG_INFINITY`, ±(3*\( \text{math.PI/4} \)) will be returned. If both arguments are 0, a domain error will not occur. If the result would cause an underflow, a range error occurs, and `math.atan2()` will return y/x.

**Errors**

No errors occur.

**Format**

```c
FLOAT
math.atan2(FLOAT y, FLOAT x)
```

**Examples**

```
1 declare local var.fo FLOAT;
2 set var.fo = math.atan2(7, -0);
```

### math.atanh()

Computes the inverse hyperbolic tangent of its argument x.

**Parameters**

- x - Floating point value representing a hyperbolic angle.

**Return value**

Upon successful completion, this function returns the inverse hyperbolic tangent of x.
If \( x \) is `math.NAN`, a NaN will be returned. If \( x \) is ±0, \( x \) will be returned.

If \( x \) is `math.POS_INFINITY` or `math.NEG_INFINITY`, a domain error occurs and a NaN will be returned. If \( x \) is subnormal, a range error occurs and \( x \) will be returned.

For finite \(|x|>1\), a domain error occurs and a NaN will be returned.

If \( x \) is ±1, a pole error occurs, and \( \text{math.atan}(x) \) will return the value of the macro `math.POS_HUGE_VAL` or `math.NEG_HUGE_VAL` with the same sign as \( x \).

**Errors**

- If the \( x \) argument is finite and not in the range -1 to 1 inclusive, or if it is `math.POS_INFINITY` or `math.NEG_INFINITY`, then `fastly.error` will be set to `ERANGE`.
- If the \( x \) argument is subnormal, or ±1, then `fastly.error` will be set to `ERANGE`.

**Format**

```
FLOAT math.atan(FLOAT x)
```

**Examples**

```c
1 declare local var.fo FLOAT;
2 set var.fo = math.atan(-1); // Returns math.NEG_INFINITY
4 if (fastly.error) {
6 set resp.http.atanh-error = fastly.error; // Returns "ERANGE"
7 }
```

---

**math.cos**

Computes the cosine of its argument \( x \), measured in radians.

**Parameters**

\( x \) - Floating point value representing an angle in radians.

**Return value**

Upon successful completion, this function returns the cosine of \( x \).

If \( x \) is `math.NAN`, a NaN will be returned. If \( x \) is ±0, the value 1.0 will be returned.

If \( x \) is `math.POS_INFINITY` or `math.NEG_INFINITY`, a domain error occurs and a NaN will be returned.

**Errors**

- If the \( x \) argument is `math.POS_INFINITY` or `math.NEG_INFINITY`, then `fastly.error` will be set to `EDOM`.

**Format**

```
FLOAT math.cos(FLOAT x)
```

**Examples**

```c
1 declare local var.fo FLOAT;
2 set var.fo = math.cos(math.PI_2);
```

---

**math.cosh**

Computes the hyperbolic cosine of its argument \( x \).

**Parameters**

\( x \) - Floating point value representing a hyperbolic angle.

**Return value**

Upon successful completion, this function returns the hyperbolic cosine of \( x \).

If \( x \) is `math.NAN`, a NaN will be returned. If \( x \) is ±0, the value 1.0 will be returned.

If \( x \) is `math.POS_INFINITY` or `math.NEG_INFINITY`, \( \text{math.POS_INFINITY} \) will be returned.
If the result would cause an overflow, a range error occurs and `math.cosh()` will return the value of the macro `math.POS_HUGE_VAL`.

**Errors**
If the result would cause an overflow, then `fastly.error` will be set to `ERANGE`.

**Format**

```c
FLOAT
math.cosh(FLOAT x)
```

**Examples**

```c
1 declare local var.fo FLOAT;
2 set var.fo = math.cosh(0);
```

### math.sin()

Computes the sine of its argument `x`, measured in radians.

**Parameters**

`x` - Floating point value representing an angle in radians.

**Return value**

Upon successful completion, this function returns the sine of `x`.

If `x` is `math.NAN`, a NaN will be returned.

If `x` is ±0, `x` will be returned.

If `x` is `math.POS_INFINITY` or `math.NEG_INFINITY`, a domain error occurs and a NaN will be returned.

If `x` is subnormal, a range error occurs and `x` will be returned.

**Errors**

- If the `x` argument is `math.POS_INFINITY` or `math.NEG_INFINITY`, then `fastly.error` will be set to `EDOM`.
- If the `x` argument is subnormal, then `fastly.error` will be set to `ERANGE`.

**Format**

```c
FLOAT
math.sin(FLOAT x)
```

**Examples**

```c
1 declare local var.fi FLOAT;
2 declare local var.fo FLOAT;
3 4 set var.fi = math.PI;
5 set var.fi /= 6;
6 set var.fo = math.sin(var.fi);
```

### math.sinh()

Computes the hyperbolic sine of its argument `x`.

**Parameters**

`x` - Floating point value representing a hyperbolic angle.

**Return value**

Upon successful completion, this function returns the hyperbolic sine of `x`.

If `x` is `math.NAN`, a NaN will be returned.

If `x` is ±0, or `math.POS_INFINITY` or `math.NEG_INFINITY`, `x` will be returned.

If `x` is subnormal, a range error occurs and `x` will be returned.

If the result would cause an overflow, a range error occurs and `math.POS_HUGE_VAL` or `math.NEG_HUGE_VAL` (with the same sign as `x`) will be returned.

**Errors**

If the `x` argument is subnormal or if the result would cause an overflow, then `fastly.error` will be set to `ERANGE`.

**Format**
FLOAT
math.sinh(FLOAT x)

Examples
1 declare local var.fo FLOAT;
2 set var.fo = math.sinh(-1);

math.sqrt()
Computes the square root of its argument x.

Parameters
x - Floating point value.

Return value
Upon successful completion, this function returns the square root of x.

- If x is math.NAN, a NaN will be returned.
- If x is ±0 or math.POS_INFINITY, x will be returned.
- If x is a finite value < -0 or math.NEG_INFINITY, a domain error occurs and a NaN will be returned.

Errors
- If the x argument is < -0 or math.NEG_INFINITY, then fastly.error will be set to EDOM.

Format
FLOAT
math.sqrt(FLOAT x)

Examples
1 declare local var.fi FLOAT;
2 declare local var.fo FLOAT;
3 set var.fi = 9.0;
4 set var.fo = math.sqrt(var.fi);

math.tan()
Computes the tangent of its argument x, measured in radians.

Parameters
x - Floating point value representing an angle in radians.

Return value
Upon successful completion, this function returns the tangent of x.

- If x is math.NAN, a NaN will be returned.
- If x is ±0, x will be returned.
- If x is math.POS_INFINITY or math.NEG_INFINITY, a domain error occurs and a NaN will be returned.
- If x is subnormal, a range error occurs and x will be returned.
- If the result would cause an overflow, a range error occurs and math.tan() will return math.POS_HUGE_VAL or math.NEG_HUGE_VAL, with the function.

Errors
- If the x argument is math.POS_INFINITY or math.NEG_INFINITY, then fastly.error will be set to EDOM.
- If the x argument is subnormal or if the result overflows, then fastly.error will be set to ERANGE.

Format
FLOAT
math.tan(FLOAT x)

Examples
```
1 declare local var.fo FLOAT;
2 set var.fo = math.tan(math.PI_4);
```

### math.tanh()

Computes the hyperbolic tangent of its argument \( x \).

**Parameters**

\( x \) - Floating point value representing a hyperbolic angle.

**Return value**

Upon successful completion, this function returns the hyperbolic tangent of \( x \).

- If \( x \) is \( \text{math.NAN} \), a NaN will be returned.
- If \( x \) is \( \pm 0 \), \( x \) will be returned.
- If \( x \) is \( \text{math.POS_INFINITY} \) or \( \text{math.NEG_INFINITY} \), \( \pm 1 \) will be returned.
- If \( x \) is subnormal, a range error occurs and \( x \) will be returned.

**Errors**

If the \( x \) argument is subnormal, then \( \text{fastly.error} \) will be set to \( \text{ERANGE} \).

**Format**

```
FLOAT
math.tanh(FLOAT x)
```

**Examples**

```
1 declare local var.fo FLOAT;
2 set var.fo = math.tanh(-1);
```

### Miscellaneous

**Miscellaneous features**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>goto</td>
<td>Performs a one-way transfer of control to another line of code. See the example for more information.</td>
</tr>
<tr>
<td>return</td>
<td>Returns (with no return value) from a custom subroutine to exit early. See the example for more information.</td>
</tr>
</tbody>
</table>

**Examples**

Use the following examples to learn how to implement the features.

**Goto**

Similar to some programming languages, goto statements in VCL allow you perform a one-way transfer of control to another line of code. It must always be forward, rather than to an earlier part of code.

This act of "jumping" allows you to do things like perform logical operations or set headers before returning lookup, error, or pass actions. It is easier to do things like jump to common error handling blocks before returning from a function. The goto statement works in custom sub

```
1 sub vcl_recv {
2     if (!req.http.Foo) {
3         goto foo;
4     }
5     foo:
6     set req.http.Foo = "1";
7 }
```

**Return**

You can use return to exit early from a custom subroutine.

```
1 sub custom_subroutine {
2     if (req.http.Cookie:user_id) {
3         return;
4     }
5     # do a bunch of other stuff
6     }
7 ```
**addr.extract_bits()**

Extracts \( \text{bit\_count} \) bits (at most 32) starting with the bit number \( \text{start\_bit} \) from the given IPv4 or IPv6 address and return them in the form of an integer.

Bit numbering starts at 0 from the right-most end of the address (the lowest order bit in the last byte of the address is bit number 0). As this address, it copies them to form the integer. In the address from which it extracts bits, the lowest order bit extracted from the first byte (if copied to the lowest order bit in the resulting integer).

If this function goes past the highest order bit in the left-most byte in the address before completing the copying of \( \text{bit\_count} \) bits, then it treats these high-order bits in the integer at zero.

The bit count can be, at most, 32. The start bit must be lower than 128. The bit count plus start bit must be, at most, 128. If the VCL using this function goes past these three constraints, then it will be rejected at compilation time.

The start bit and bit count must be constant values.

IPv6 addresses are 128 bits and IPv4 addresses are 32 bits. This function behaves as if an IPv4 address were padded with zeros on the left applied to an address that is neither IPv4 nor IPv6, then it will return 0.

**Format**

\[
\text{INTEGER} \\
\text{addr.extract_bits(IP, start\_bit INTEGER, bit\_count INTEGER)}
\]

**Examples**

```plaintext
1 if (addr.extract_bits(server.ip, 0, 8) == 7) {
2    # received on an IPv4 address that ends in ".7" or an IPv6 address that ends in "07"
3 }
```

**addr.is_ipv4()**

Returns true if the address family of the given address is IPv4.

**Format**

\[
\text{BOOL} \\
\text{addr.is_ipv4(IP ip)}
\]

**Examples**

```plaintext
1 if (addr.is_ipv4(client.ip)) {
2    # the client connected over IPv4 */
3 }
```

**addr.is_ipv6()**

Returns true if the address family of the given address is IPv6.

**Format**

\[
\text{BOOL} \\
\text{addr.is_ipv6(IP ip)}
\]

**Examples**

```plaintext
1 if (addr.is_ipv6(client.ip)) {
2    # the client connected over IPv6 */
3 }
```

**http_status_matches()**

Determines whether the HTTP status matches or does not match any of the statuses in the supplied \( \text{fmt} \) string.

Returns true when the status matches any of the strings and returns false otherwise. If \( \text{fmt} \) is prefixed with \( ! \), returns true when the status does not match any of the strings and returns false if it does. Statuses in the string are separated by commas.

This function is not prefixed with the \( \text{std.} \) namespace.

**Format**

\[
\text{BOOL} \\
\text{http_status_matches(INTEGER status, STRING fmt)}
\]

**Examples**

```plaintext
```
```plaintext
1  if (http_status_matches(beresp.status, "[200,301,302]") { 
2    set obj.cacheable = 0; 
3 }
```

### if()

Implements a ternary operator for strings; if the expression is true, it returns `value-when-true`; if the expression is false, it returns `value-when-false`.

You can use `if()` as a construct to make simple conditional expressions more concise.

**Format**

```plaintext
STRING
if(BOOL expression, STRING value-when-true, STRING value-when-false)
```

**Examples**

```plaintext
1  set req.http.foo-status = if(req.http.foo, "present", "absent");
```

### setcookie.get_value_by_name()

Returns a value associated with the `cookie_name` in the `Set-Cookie` header contained in the HTTP response indicated by `where`. An unse is not found or on error. In the `vcl_fetch` method, the `beresp` response is available. In `vcl_deliver` and `vcl_log`, the `resp` response is If multiple cookies of the same name are present in the response, the value of the last one will be returned.

When this function does not have enough memory to succeed, the request is failed.

This function conforms to **RFC6265**.

**Format**

```plaintext
STRING
setcookie.get_value_by_name(ID where, STRING cookie_name)
```

**Examples**

```plaintext
1  set resp.http.MyValue = setcookie.get_value_by_name(resp, "myvalue");
```

### std.collect()

Combines multiple instances of the same header into one. The headers are joined using the optional separator character parameter. If omitted, the separator character defaults to `;`. It can be any one-character constant. For example, `;` is a useful separator for combining multiple Set-Cookie headers should not be combined into a single header as this might lead to unexpected results on the browser side.

**Format**

```plaintext
VOID
std.collect(STRING header [, STRING separator_character])
```

**Examples**

```plaintext
1  # For a request with these Cookie headers:
2  # Cookie: name1=value1
3  # Cookie: name2=value2
4  std.collect(req.http.Cookie, ";");
5  # req.http.Cookie is now "name1=value1; name2=value2"
```

### subfield()

Provides a means to access subfields from a header like `Cache-Control`, `Cookie`, and `Edge-Control` or individual parameters from the `Set-Cookie` field.

The optional separator character parameter defaults to `;`. It can be any one-character constant. For example, `;` is a useful separator for combining multiple Set-Cookie headers.

This functionality is also achievable by using the `:` accessor within a variable name. When the subfield is a valueless token (like "private" in `Control: max-age=1200, private`), an empty string is returned. The `:` accessor also works for retrieving variables in a cookie.

This function is not prefixed with the `std` namespace.

**Format**

```plaintext
STRING
subfield(STRING header, STRING fieldname [, STRING separator_character])
```

**Examples**
if (subfield(beresp.http.Cache-Control, "private")) {
  return (pass);
}

set beresp.ttl = beresp.http.Cache-Control:max-age;

if (subfield(beresp.http.Set-Cookie, "httponly", ";")) {
  #....
}

set req.http.value-of-foo = subfield(req.url.qs, "foo", ";");

---

Miscellaneous Variables

- **bereq.url.basename**
  
  Same as `req.url.basename`, except for use between Fastly and your origin servers.

  **Type**
  
  STRING

  **Accessibility**
  
  Readable From
  
  All subroutines

- **bereq.url.dirname**
  
  Same as `req.url.dirname`, except for use between Fastly and your origin servers.

  **Type**
  
  STRING

  **Accessibility**
  
  Readable From
  
  All subroutines

- **bereq.url.qs**
  
  The query string portion of `bereq.url`. This will be from immediately after the `?` to the end of the URL.

  **Type**
  
  STRING

  **Accessibility**
  
  Readable From
  
  All subroutines

- **bereq.url**
  
  The URL sent to the backend. Does not include the host and scheme, meaning in `www.example.com/index.html`, `bereq.url` would conta

  **Type**
  
  STRING

  **Accessibility**
  
  Readable From
  
  All subroutines

- **beresp.backend.ip**
  
  The IP of the backend this response was fetched from (backported from Varnish 3).

  **Type**
  
  IP

  **Accessibility**
  
  Readable From
  
  All subroutines

- **beresp.backend.name**
The name of the backend this response was fetched from (backported from Varnish 3).

**Type**  
STRING

**Accessibility**  
Readable From  
- vcl_fetch

**beresp.backend.port**
The port of the backend this response was fetched from (backported from Varnish 3).

**Type**  
INTEGER

**Accessibility**  
Readable From  
- vcl_fetch

**beresp.grace**
Defines how long an object can remain overdue and still have Varnish consider it for grace mode. Fastly has implemented stale-if-error implementation of beresp.grace.

**Type**  
RTIME

**Accessibility**  
Readable From  
- vcl_fetch

**beresp.hipaa**
Specifies that content not be cached in non-volatile memory to help customers meet HIPAA security requirements. See our guide on HIPAA instructions on enabling this feature for your account.

**Type**  
BOOL

**Accessibility**  
Readable From  
- vcl_fetch

**beresp.pci**
Specifies that content be cached in a manner that satisfies PCI DSS requirements. See our PCI compliance description for instructions on enabling this feature for your account.

**Type**  
BOOL

**Accessibility**  
Readable From  
- vcl_fetch

**client.ip**
The IP address of the client making the request.

**Type**  
IP

**Accessibility**  
Readable From  
All subroutines

**client.port**
Returns the remote client port. This could be useful as a seed that returns the same value both in an ESI and a top level request. For example, `client.ip` and `client.port` to get a value used both in ESI and the top level request.

**Type**

`INTEGER`

**Accessibility**

Readable From

All subroutines

- `client.requests`

Tracks the number of requests received by Varnish over a persistent connection. Over an HTTP/2 connection, tracks the number of multiplexed requests.

**Type**

`INTEGER`

**Accessibility**

Readable From

All subroutines

- `client.socket.pace`

Ceiling rate in kilobytes per second for bytes sent to the client.

This rate accounts for header sizes and retransmits, so the application level rate might be different from the one set here.

**Type**

`INTEGER`

**Accessibility**

Readable From

All subroutines

- `fastly.error`

Contains the error code raised by the last function, otherwise not set.

**States**

- `EPARSENUM`: Number parsing failed.
- `ERANGE`: Numerical result out of range.
- `EREGRECUR`: Call to regex routine failed because of recursion limits.
- `EREGSUB`: Call to regex routine failed (generic).
- `ESESOM`: Out of workspace memory.
- `EDOM`: Domain error. This occurs for a mathematical function that is not defined for a particular value. Formally, that value is not consic domain. For example, division by zero, or `var.x % 5` where `var.x` is a floating point infinity.
- `ESYNTHOOM`: Synthetic response overflow.

**Type**

`STRING`

**Accessibility**

Readable From

All subroutines

- `req.backend.healthy`

Whether or not this backend, or recursively any of the backends under this director, is considered healthy. The random director has the addi `quorum` threshold must be met by the healthy backends under the director. The health state is determined by: healthcheck results, whether connection to be made to the backend based on the number of currently used connections and the backend's `max_connections` setting, a saintmode settings.

**Type**

`BOOL`

**Accessibility**

Readable From

All subroutines
• vcl_deliver
• vcl_error
• vcl_fetch
• vcl_hash
• vcl_hit
• vcl_miss
• vcl_pass
• vcl_recv

:req.backend.is_cluster
True if this backend, or recursively any of the backends under this director, is a cluster backend. False otherwise.

Type
BOOL

Accessibility
Readable From
All subroutines

:req.backend.is_origin
True if this backend, or recursively any of the backends under this director, is not a shield backend. False otherwise.

Type
BOOL

Accessibility
Readable From

:req.backend.is_shield
True if this backend, or recursively any of the backends under this director, is a shield backend. False otherwise.

Type
BOOL

Accessibility
Readable From
All subroutines

:req.backend
The backend to use to service the request.

Type
BACKEND

Accessibility
Readable From
All subroutines

:req.body.base64
Same as req.body, except the request body is encoded in Base64, which handles null characters and allows representation of binary bodi

Type
STRING

Accessibility
Readable From
All subroutines
**req.body**
The request body. Using this variable for binary data will truncate at the first null character. Limited to 8KB in size. Exceeding the limit results being blank. The variable `req.postbody` is an alias for `req.body`.

**Type**
STRING

**Accessibility**
Readable From
All subroutines

**req.grace**
Defines how long an object can remain overdue and still have Varnish consider it for grace mode.

**Type**
RTIME

**Accessibility**
Readable From
All subroutines

**req.http.host**
The full host name, without the path or query parameters.

**Examples**
For example, in the request `www.example.com/index.html?a=1&b=2`, `req.http.host` will contain `www.example.com`.

**Type**
STRING

**Accessibility**
Readable From
All subroutines

**req.is_ipv6**
Indicates whether the request was made using IPv6 or not.

**Type**
BOOL

**Accessibility**
Readable From
- vcl_recv
- vcl_hash
- vcl_deliver
- vcl_log

**req.restarts**
Counts the number of times the VCL has been restarted.

**Type**
INTEGER

**Accessibility**
Readable From
All subroutines

**req.url.basename**
The file name specified in a URL.

**Examples**
In the request `www.example.com/l/hello.gif?foo=bar`, `req.url.basename` will contain `hello.gif`.

**Type**
**STRING**

**Accessibility**

Readable From

All subroutines

- `req.urldirname`

The directories specified in a URL.

**Examples**

- In the request `www.example.com/1/hello.gif?foo=bar`, `req.urldirname` will contain `/1`.
- In the request `www.example.com/5/inner/hello.gif?foo=bar`, `req.urldirname` will contain `/5/inner`.

**Type**

- `STRING`

**Accessibility**

Readable From

All subroutines

- `req.url.ext`

The file extension specified in a URL.

**Examples**

- In the request `www.example.com/index.html?a=1&b=2`, `req.url.ext` will contain `html`.

**Type**

- `STRING`

**Accessibility**

Readable From

All subroutines

- `req.url.path`

The full path, without any query parameters.

**Examples**

- In the request `www.example.com/inner/index.html?a=1&b=2`, `req.url.path` will contain `/inner/index.html`.

**Type**

- `STRING`

**Accessibility**

Readable From

All subroutines

- `req.url.qs`

The query string portion of `req.url`. This will be from immediately after the `?` to the end of the URL.

**Examples**

- In the request `www.example.com/index.html?a=1&b=2`, `req.url.qs` will contain `a=1&b=2`.

**Type**

- `STRING`

**Accessibility**

Readable From

All subroutines

- `req.url`

The full path, including query parameters.

**Examples**

- In the request `www.example.com/index.html?a=1&b=2`, `req.url` will contain `/index.html?a=1&b=2`. 
Type
STRING

Accessibility
Readable From
All subroutines

⚠ stale.exists
Specifies if a given object has stale content in cache. Returns true or false.

Type
STRING

Accessibility
Readable From
All subroutines

**Query string manipulation**

**Examples**

In your VCL, you could use `querystring.regfilter_except` as follows:

```vcl
sub vcl_recv {
    # return this URL with only the parameters that match this regular expression
    set req.url = querystring.regfilter_except(req.url, "^(q|p)$");
}
```

You can use `querystring.regfilter` to specify a list of arguments that must not be removed (everything else will be) with a negative look-

```vcl
set req.url = querystring.regfilter(req.url, "^(?!param1|param2)");
```

**Query string manipulation Functions**

⚠ boltsort.sort()

Alias of `querystring.sort`.

**Format**

STRING
boltsort.sort(STRING url)

**Examples**

```vcl
set req.url = boltsort.sort(req.url);
```

⚠ querystring.add()

Returns the given URL with the given parameter name and value appended to the end of the query string. The parameter name and value w added to the query string.

**Format**

STRING
querystring.add(STRING, STRING, STRING)

**Examples**

```vcl
set req.url = querystring.add(req.url, "foo", "bar");
```

⚠ querystring.clean()

Returns the given URL without empty parameters. The query-string is removed if empty (either before or after the removal of empty paramet with an empty value does not constitute an empty parameter, so a query string "?something" would not be cleaned.

**Format**

STRING
querystring.clean(STRING)

**Examples**

```vcl
set req.url = querystring.clean(req.url);
```
**querystring.filter_except()**

Returns the given URL but only keeps the listed parameters.

**Format**

```STRING
querystring.filter_except(STRING, STRING_LIST)
```

**Examples**

```bash
1 set req.url = querystring.filter_except(req.url, 
2   "q" + querystring.filtersep() + "p");
```

**querystring.filter()**

Returns the given URL without the listed parameters.

**Format**

```STRING
querystring.filter(STRING, STRING_LIST)
```

**Examples**

```bash
1 set req.url = querystring.filter(req.url, 
2   "utm_source" + querystring.filtersep() + 
3   "utm_medium" + querystring.filtersep() + 
4   "utm_campaign");
```

**querystring.filtersep()**

Returns the separator needed by the `querystring.filter()` and `querystring.filter_except()` functions.

**Format**

```STRING
querystring.filtersep()
```

**Examples**

```bash
1 set req.url = querystring.filter(req.url, 
2   "utm_source" + querystring.filtersep() + 
3   "utm_medium" + querystring.filtersep() + 
4   "utm_campaign");
```

**querystring.globfilter_except()**

Returns the given URL but only keeps the parameters matching a glob.

**Format**

```STRING
querystring.globfilter_except(STRING, STRING)
```

**Examples**

```bash
1 set req.url = querystring.globfilter_except(req.url, "sess*");
```

**querystring.globfilter()**

Returns the given URL without the parameters matching a glob.

**Format**

```STRING
querystring.globfilter(STRING, STRING)
```

**Examples**

```bash
1 set req.url = querystring.globfilter(req.url, "utm_*");
```

**querystring.regfilter_except()**

Returns the given URL but only keeps the parameters matching a regular expression. Groups within the regular expression are treated as if they are capturing groups. For example:
The `key-(\[0-9]\|\w)=(.*)-(.*)` pattern shown here behaves as if it were written as a non-capturing group, "key-(?:[0-9]\|\w)". ensuring the contents of re.group.2 are not affected by the call to `querystring.regfilter_except()`. 

**Format**

```
STRING
querystring.regfilter_except(STRING, STRING)
```

**Examples**

```
1 set req.url = querystring.regfilter_except(req.url, "^(q|p)$");
```

**querystring.regfilter()**

Returns the given URL without the parameters matching a regular expression. Groups within the regular expression are treated as if they were separate non-capturing groups. For example:

```
1 if (req.url.qs ~ "key-(?:[0-9]\|\w)=(.*)-(.*)") { # captures to re.group.1 and re.group.2
2    set req.url = querystring.regfilter(req.url, "key-([0-9]\|\w)"); # does not capture
3    set req.http.X-Key-1 = re.group.1;
4    set req.http.X-Key-2 = re.group.2;
5 }
```

The "key-(\[0-9]\|\w)" pattern shown here behaves as if it were written as a non-capturing group, "key-(?:[0-9]\|\w)", ensuring the contents of re.group.2 are not affected by the call to `querystring.regfilter()`. 

**Format**

```
STRING
querystring.regfilter(STRING, STRING)
```

**Examples**

```
1 set req.url = querystring.regfilter(req.url, "utm_.*");
```

**querystring.remove()**

Returns the given URL with its query-string removed.

**Format**

```
STRING
querystring.remove(STRING)
```

**Examples**

```
1 set req.url = querystring.remove(req.url);
```

**querystring.set()**

Returns the given URL with the given parameter name set to the given value, replacing the original value and removing any duplicates. If the parameter name is not present in the query string, the parameter will be appended with the given value to the end of the query string. The parameter name and value will be URL encoded.

**Format**

```
STRING
querystring.set(STRING, STRING, STRING)
```

**Examples**

```
1 set req.url = querystring.set(req.url, "foo", "baz");
```

**querystring.sort()**

Returns the given URL with its query-string sorted. For example, `querystring.sort("/foo?b=1&a=2&c=3")` returns "/foo?b=1&a=2&c=3".

**Format**

```
STRING
querystring.sort(STRING)
```
STRING
querystring.sort(STRING)

Examples
1 set req.url = querystring.sort(req.url);

Randomness

⚠️ WARNING: We use BSD random number functions from the GNU C Library, not true randomizing sources. These VCL functions should not be used for cryptographic or security purposes.

Random strings

Use the function `randomstr(length [, characters])`. When characters aren’t provided, the default will be the 64 characters of A-Za-z0-123450

1 sub vcl_deliver {
  2 set resp.http.Foo = "randomstuff=" randomstr(10);
  3 set resp.http.Bar = "morsecode=" randomstr(50, ",.-"); # 50 dots and dashes
  4 }

Random content cookies in pure VCL

1 sub vcl_deliver {
  2 add resp.http.Set-Cookie = "somerandomstuff=" randomstr(10) "; expires=" now + 180d "; path=/";
  3 }

This adds a cookie named “somerandomstuff” with 10 random characters as value, expiring 180 days from now.

Random decisions

Use the function `randombool( _numerator_, _denominator_ )`, which has a numerator/denominator chance of returning true.

1 sub vcl_recv {
  2 if (randombool(1, 4)) {
  3    set req.http.X-AB = "A";
  4  } else {
  5    set req.http.X-AB = "B";
  6  }
  7 }

This will add a X-AB header to the request, with a 25% (1 out of 4) chance of having the value "A", and 75% chance of having the value "B"

The `randombool()` function accepts INT function return values, so you could do something this:

1 if (randombool(stdatoi(req.http.Some-Header), 100)) {
  2  # do something
  3 }

Another function, `randombool_seeded()`, takes an additional seed argument. Results for a given seed will always be the same. For instance of the response header will always be no:

1 if (randombool_seeded(50, 100, 12345)) {
  2    set resp.http.Seeded-Value = "yes";
  3  } else {
  4    set resp.http.Seeded-Value = "no";
  5 }

This could be useful for stickiness. For example, if you based the seed off of something that identified a user, you could perform A/B testing cookie.

⚠️ WARNING: The `randombool` and `randombool_seeded` functions do not use secure random numbers and should not be used for cryptographic purposes.

Randomness Functions

- `randombool_seeded()`
  
  Identical to `randombool`, except takes an additional parameter, which is used to seed the random number generator.

  This does not use secure random numbers and should not be used for cryptographic purposes.

  This function is not prefixed with the `std` namespace.

Format
BOOL randombool_seeded(INTEGER numerator, INTEGER denominator, INTEGER seed)

Examples

```
1 set req.http.my-hmac = digest.hmac_sha256("sekrit", req.http.X-Token);
2 set req.http.hmac-chopped = regsub(req.http.my-hmac, "\'^\(............\).\$'\,"\1");
3 if (randombool_seeded(5, 100, std.strtol(req.http.hmac-chopped, 16))) {
4   set req.http.X-Allowed = "true";
5 } else {
6   set req.http.X-Allowed = "false";
7 }
```

**randombool()**

Returns a random, boolean value. The result is true when, given a pseudorandom number \( r \), \( \text{RAND_MAX} \times \text{numerator} > r \times \text{denominator} \).

This does not use secure random numbers and should not be used for cryptographic purposes.

This function is not prefixed with the `std.` namespace.

**Format**

```cpp
BOOL randombool(INTEGER numerator, INTEGER denominator)
```

**Examples**

```
1 if (randombool(1, 10)) {
2   set req.http.X-ABTest = "A";
3 } else {
4   set req.http.X-ABTest = "B";
5 }
```

**randomint_seeded()**

Identical to `randomint`, except takes an additional parameter used to seed the random number generator.

This does not use secure random numbers and should not be used for cryptographic purposes.

This function is not prefixed with the `std.` namespace.

**Format**

```cpp
INTEGER randomint_seeded(INTEGER from, INTEGER to, INTEGER seed)
```

**Examples**

```
1 if (randomint_seeded(1, 5, user_id) < 5) {
2   set req.http.X-ABTest = "A";
3 } else {
4   set req.http.X-ABTest = "B";
5 }
6 if (randomint_seeded(-1, 0, 555) == -1) {
7   set req.http.X-ABTest = "A";
8 } else {
9   set req.http.X-ABTest = "B";
10 }
```

**randomint()**

Returns a random integer value between `from` and `to`, inclusive.

This does not use secure random numbers and should not be used for cryptographic purposes.

This function is not prefixed with the `std.` namespace.

**Format**

```cpp
INTEGER randomint(INTEGER from, INTEGER to)
```

**Examples**
```c
if (randomint(0, 99) < 5) {
    set req.http.X-ABTest = "A";
} else {
    set req.http.X-ABTest = "B";
}
if (randomint(-1, 0) == -1) {
    set req.http.X-ABTest = "A";
} else {
    set req.http.X-ABTest = "B";
}
```

---

**randomstr()**

Returns a random string of length `len` containing characters from the supplied string `characters`.

This does not use secure random functions and should not be used for cryptographic purposes.

This function is not prefixed with the `std` namespace.

**Format**

```
STRING
randomstr(INTEGER len, STRING characters)
```

**Examples**

```c
set req.http.X-RandomHexNum = randomstr(8, "1234567890abcdef");
```

---

### Segmented Caching

#### Segmented Caching Variables

- **fastly.segmented_caching.autopurged**

  Whether an inconsistency encountered during Segmented Caching processing led to the system automatically enqueuing a purge request.

  **Type**
  
  `BOOL`

  **Accessibility**
  
  Readable From
  
  - `vcl_log`

- **fastly.segmented_caching.block_number**

  A zero-based counter identifying the file fragment being processed. This variable will evaluate to `-1` in cases when it is not applicable, such as when Segmented Caching is not enabled for the request.

  **Type**
  
  `INTEGER`

  **Accessibility**
  
  Readable From
  
  - `vcl_log`

- **fastly.segmented_caching.cancelled**

  Whether Segmented Caching processing was enabled and cancelled by a non-206 response.

  **Type**
  
  `BOOL`

  **Accessibility**
  
  Readable From
  
  - `vcl_log`

- **fastly.segmented_caching.client_req.is_open_ended**

  Whether the client’s request leaves the upper bound of the range open. This variable will evaluate to `false` when Segmented Caching is not enabled.

  **Type**
  
  `BOOL`

  **Accessibility**
  
  Readable From
  
  - `vcl_log`
Readable From
- `vcl_log`

**fastly.segmented_caching.client_req.is_range**

Whether the client’s request is a range request. This variable will evaluate to `false` when Segmented Caching is not enabled for the request (is present).

**Type**
- `BOOL`

**Accessibility**
- Readable From `vcl_log`

**fastly.segmented_caching.client_req.range_high**

The upper bound of the client’s requested range. This variable will evaluate to `-1` in cases when it is not applicable, such as when Segmented Caching is not enabled for the request. It will evaluate to `9223372036854775807` (2^63-1) for an open-ended requested range (when `fastly.segmented_caching.client_req.is_open_ended` is true).

**Type**
- `INTEGER`

**Accessibility**
- Readable From `vcl_log`

**fastly.segmented_caching.client_req.range_low**

The lower bound of the client’s requested range. This variable will evaluate to `-1` in cases when it is not applicable, such as when Segmented Caching is not enabled for the request.

**Type**
- `INTEGER`

**Accessibility**
- Readable From `vcl_log`

**fastly.segmented_caching.completed**

Whether Segmented Caching processing was enabled and cancelled by a non-206 response.

**Type**
- `BOOL`

**Accessibility**
- Readable From `vcl_log`

**fastly.segmented_caching.error**

The reason why Segmented Caching processing failed. This variable will evaluate to `NULL` if Segmented Caching was not enabled, or if Segmented Caching completed successfully or was cancelled by a non-206 response.

**Type**
- `STRING`

**Accessibility**
- Readable From `vcl_log`

**fastly.segmented_caching.failed**

Whether Segmented Caching processing was enabled and ended in a failure. When this variable evaluates to `true`, the variable `fastly.segmented_caching.error` will evaluate to a string describing the nature of the failure.

**Type**
- 

---

https://docs.fastly.com/vcl/aio
**BOOL**

**Accessibility**

**Readable From**

- `vcl_log`

`fastly.segmented_caching.is_inner_req`

Whether VCL is running in the context of a sub-request that is retrieving a fragment of a file. If using the default 1MB object size, there will be a request back to origin.

**Type**

`BOOL`

**Accessibility**

**Readable From**

- `vcl_log`

`fastly.segmented_caching.is_outer_req`

Whether VCL is running in the context of a request that is assembling file fragments into a response.

**Type**

`BOOL`

**Accessibility**

**Readable From**

- `vcl_log`

`fastly.segmented_caching.obj.complete_length`

The size of the whole file in bytes. The information comes from the `Content-Range` response header field in the first fragment accessed when `Segmented Caching` is enabled for the request. This variable will evaluate to `-1` in cases when it is not applicable, such as when Segmented Caching is not enabled for the request.

**Type**

`INTEGER`

**Accessibility**

**Readable From**

- `vcl_log`

`fastly.segmented_caching.rounded_req.range_high`

The upper bound of the rounded block being processed. This variable will evaluate to `-1` in cases when it is not applicable, such as when Segmented Caching is enabled for the request.

**Type**

`INTEGER`

**Accessibility**

**Readable From**

- `vcl_log`

`fastly.segmented_caching.rounded_req.range_low`

The lower bound of the rounded block being processed. This variable will evaluate to `-1` in cases when it is not applicable, such as when Segmented Caching is enabled for the request.

**Type**

`INTEGER`

**Accessibility**

**Readable From**

- `vcl_log`

`fastly.segmented_caching.total_blocks`

The number of fragments needed for assembling this response. This variable will evaluate to `-1` in cases when it is not applicable, such as when Segmented Caching is not enabled for the request.
**Server Variables**

### `server.datacenter`

A code representing one of Fastly's POP locations.

**Type**

INTEGER

**Accessibility**

Readable From

- `vcl_log`

### `server.hostname`

Hostname of the server (e.g., `cache-jfk1034`).

**Type**

STRING

**Accessibility**

Readable From

All subroutines

### `server.identity`

Same as `server.hostname` but also explicitly includes the datacenter name (e.g., `cache-jfk1034-JFK`).

**Type**

STRING

**Accessibility**

Readable From

All subroutines

### `server.region`

A code representing the general region of the world in which the POP location resides. One of the following:

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Approximate Geographic Location of Fastly POPs</th>
</tr>
</thead>
<tbody>
<tr>
<td>APAC</td>
<td>Australia and New Zealand</td>
</tr>
<tr>
<td>Asia</td>
<td>throughout the Asian continent (except India)</td>
</tr>
<tr>
<td>Asia-South</td>
<td>southern Asia</td>
</tr>
<tr>
<td>EU-Central</td>
<td>the central European continent</td>
</tr>
<tr>
<td>EU-East</td>
<td>the eastern European continent</td>
</tr>
<tr>
<td>EU-West</td>
<td>the western European continent</td>
</tr>
<tr>
<td>North-America</td>
<td>Canada</td>
</tr>
<tr>
<td>SA-East</td>
<td>eastern South America</td>
</tr>
<tr>
<td>SA-North</td>
<td>northern South America</td>
</tr>
<tr>
<td>SA-South</td>
<td>southern South America</td>
</tr>
<tr>
<td>South-Africa</td>
<td>the southern regions of Africa</td>
</tr>
<tr>
<td>US-Central</td>
<td>the central United States</td>
</tr>
<tr>
<td>US-East</td>
<td>the eastern United States</td>
</tr>
<tr>
<td>US-West</td>
<td>the western United States</td>
</tr>
</tbody>
</table>
Type

All subroutines

Size
Size Variables

береж.body_bytes_written
Total body bytes written to a backend. Does not include header bytes.

Type

Accessibility
Readable From

• vcl_fetch
• vcl_deliver
• vcl_log

береж.header_bytes_written
Total header bytes written to a backend.

Type

Accessibility
Readable From

• vcl_fetch
• vcl_deliver
• vcl_log

req.body_bytes_read
Total body bytes read from the client generating the request.

Type

Accessibility
Readable From

• vcl_deliver
• vcl_log

req.bytes_read
Total bytes read from the client generating the request.

Type

Accessibility
Readable From

• vcl_deliver
• vcl_log

req.header_bytes_read
Total header bytes read from the client generating the request.

Type

STRING
Accessibility
Readable From
All subroutines

resp.body_bytes_written
Body bytes to send to the client in the response.

Type
STRING

Accessibility
Readable From
- [vcl_log]

resp.bytes_written
Total bytes to send to the client in the response.

Type
STRING

Accessibility
Readable From
- [vcl_log]

resp.completed
Whether the response completed successfully or not.

Type
BOOL

Accessibility
Readable From
- [vcl_log]

resp.header_bytes_written
How many bytes were written for the header of a response.

Type
STRING

Accessibility
Readable From
- [vcl_log]

String manipulation
String manipulation Functions

cstr_escape()
Escapes bytes from a string using C-style escape sequences.

The escaping rules in priority order are as follows:

1. if the byte is the doublequote (0x22), it is escaped as `\"` (backslash doublequote)
2. if the byte is the backslash (0x5C), it is escaped as `\` (double backslash)
3. if the byte is one of the following control characters, it is escaped as follows:
   - `\b` (0x08, backspace)
   - `\t` (0x09, horizontal tab)
   - `\n` (0x0A, newline)
   - `\v` (0x0B, vertical tab)
   - `\r` (0x0D, carriage return)
4. if the byte is less than or equal to 0x1F, or it is greater or equal to 0x7F (in other words, a control character not explicitly listed above), \( HH \) is the hexadecimal value of the byte.

5. if none of the above matched, the byte is passed through as-is: for example \( a \) for 0x61

**TIP:** If you are escaping JSON strings, use `json.escape()` instead.

This function is not prefixed with the `std.` namespace.

**Format**

```
STRING cstr_escape(STRING string)
```

**Examples**

```c
# var.escaped is set to: city="london"
declare
local var.escaped STRING;
set var.escaped = "city=%22" + cstr_escape(client.geo.city.ascii) + "%22"
```

**json.escape()**

Escapes characters of a UTF-8 encoded Unicode string using JSON-style escape sequences.

**Format**

```
STRING json.escape(STRING string)
```

**Examples**

```c
declare
local var.json STRING;
set var.json = "\{%22city%22: %22" + json.escape(client.geo.city.utf8) + "%22}";
```

**regsub()**

Replaces the first occurrence of pattern, which is a Perl-compatible regular expression, in input with replacement. If no match is found

Calls to `regsub` do not set `re.group.*`

This function may fail to make a replacement if the regular expression recurses too heavily. Such a situation may occur with lookahead and other recurring non-regular expressions. In this case, `fastly.error` is set to `EREGRECUR`.

This function is not prefixed with the `std.` namespace.

**Format**

```
STRING regsub(STRING input, STRING pattern, STRING replacement)
```

**Examples**

```c
set req.url = regsub(req.url, "\?.*$", "");
```

**regsuball()**

Replaces all occurrences of pattern, which may be a Perl-compatible regular expression, in input with replacement. If no matches are made.

Once a replacement is made, substitutions continue from the end of the replaced buffer. Therefore, `regsuball("aaa", "a", "aa")` will return instead of recursing indefinitely.

This function may fail to make a replacement if the regular expression recurses too heavily. Such a situation may occur with lookahead and other recurring non-regular expressions. In this case, `fastly.error` is set to `EREGRECUR`.

This function is not prefixed with the `std.` namespace.

**Format**

```
STRING regsuball(STRING input, STRING pattern, STRING replacement)
```

**Examples**

```c
set req.url = regsuball(req.url, "\\", "%2520");
```
std.anystr2ip

Converts the string `addr` to an IP address (IPv4 or IPv6). If conversion fails, `fallback` will be returned.

This function accepts a wider range of formats than `std.str2ip()`: Each number may be specified in hexadecimal (`0x...`), octal (`0...`), or may be fewer than four numbers, in which case the last number is responsible for the remaining bytes of the IP. For example, `0x8.010.2056`

We recommend using a fallback IP address that's meaningful for your particular Fastly service.

**Format**

```go
IP
std.anystr2ip(STRING addr, STRING fallback)
```

**Examples**

```go
1 if (std.anystr2ip("0xc0.0.01001", "192.0.2.2") ~ my_acl) {
  2  ...
  3 }
```

std.atof

Takes a string (which represents a float) as an argument and returns its value. Behaves as if calling `std.strtof()` with a base of 10.

**Format**

```go
FLOAT
std.atof(STRING s)
```

**Examples**

```go
1 if (std.atof(req.http.X-String) > 21.82) {
  2  set req.http.X-TheAnswer = "Found";
  3 }
```

std.atoi

Takes a string (which represents an integer) as an argument and returns its value. Behaves as if calling `std.strtol()` with a base of 10.

**Format**

```go
INTEGER
std.atoi(STRING s)
```

**Examples**

```go
1 if (std.atoi(req.http.X-Decimal) == 42) {
  2  set req.http.X-TheAnswer = "Found";
  3 }
```

std.ip

An alias of `std.str2ip()`.

We recommend using a fallback IP address that's meaningful for your particular Fastly service.

**Format**

```go
IP
std.ip(STRING addr, STRING fallback)
```

**Examples**

```go
1 if (std.ip(req.http.Fastly-Client-IP, "192.0.2.2") ~ my_acl) {
  2  ...
  3 }
```

std.ip2str

Converts the IP address (v4 or v6) to a string.

**Format**

```go
STRING
std.ip2str(IP ip)
```

**Examples**

```go
1
2
3
```
1 if (std.ip2str(std.str2ip(req.http.Client-IP, "192.0.2.2")) ~ my_acl) {
  2  ...
  3 }

### std.prefixof()

True if the string `s` begins with the string `begins_with`. An empty string is not considered a prefix.

Returns false otherwise.

**Format**

```plaintext
BOOL
std.prefixof(STRING s, STRING begins_with)
```

**Examples**

```plaintext
1 set req.http.X-ps = std.prefixof("greenhouse", "green");
```

### std.str2ip()

Converts the string representation of an IP address (IPv4 or IPv6) into an `IPtype`. If conversion fails, the fallback will be returned. The string address representation in the standard format such as `192.0.2.2` and `2001:db8::1`. This function does not support looking up an IP addr

We recommend using a fallback IP address that’s meaningful for your particular Fastly service.

**Format**

```plaintext
IP
std.str2ip(STRING addr, STRING fallback)
```

**Examples**

```plaintext
1 if (std.str2ip(req.http.Client-IP, "192.0.2.2") ~ my_acl) {
  2  ...
  3 }
```

### std.strlen()

Returns the length of the string. For example, `std.strlen("Hello world!")` will return `12` because the string includes whitespaces and

**Format**

```plaintext
INTEGER
std.strlen(STRING s)
```

**Examples**

```plaintext
1 if (std.strlen(req.http.Cookie) > 1024) {
  2  unset req.http.Cookie;
  3 }
```

### std.strpad()

This function constructs a string containing the input string `s` padded out with `pad` to produce a string of the given `width`. The padding is necessary and cut short when `width` is reached.

Note that `width` is given in bytes and this function will cut short paddings with multi-byte encodings.

Negative `width` left-justifies `s` by placing padding to the right. Positive `width` right-justifies `s` by placing padding to the left. If `width` is the length of `s`, then no padding is performed.

If `pad` is the empty string, then no padding is performed and the unmodified string `s` is returned.

**Format**

```plaintext
STRING
std.strpad(STRING s, INTEGER width, STRING pad)
```

**Examples**

```plaintext
1 set var.s = std.strpad("abc", -10, ":-: "); # produces "abc-=-=-=-"

1 set var.s = std.strpad("abc", 10, ":-: "); # produces "-=-=-=-abc"
```
```c
1 declare local var.n INTEGER;
2 set var.n = std_strlen("abcd");
3 set var.n *= 3;
4 set var.s = std_strpad("", var.n, "abcd"); # repeat "abcd" three times
```

### std.strrep()

Repeats the given string \( n \) times. If \( n \) is a negative value, it is taken to mean zero.

**Format**

```c
STRING
std.strrep(STRING s, INTEGER n)
```

**Examples**

```c
1 set var.s = std.strrep("abc", 3); # produces "abcabcabc"
```

### std.strrev()

Reverses the given string. This function does not support UTF-8 encoded strings.

**Errors**

This function will set `fastly.error` to `EUTF8` if the input string \( s \) is UTF-8 encoded.

**Format**

```c
STRING
std.strrev(STRING s)
```

**Examples**

```c
1 set var.s = std.strrev("abc"); # produces "cba"
```

### std.strstr()

Returns the part of `haystack` string starting from and including the first occurrence of `needle` until the end of `haystack`.

**Format**

```c
STRING
std.strstr(STRING haystack, STRING needle)
```

**Examples**

```c
1 set req.http.X-qs = std.strstr(req.url, "?");
```

### std.strtof()

Converts the string \( s \) to a float value with the given base \( base \). The value \( base \) must be a constant integer expression (variables are not allowed). The following string formats are supported for finite values:

- Decimal (base 10) floating point syntax. For example, \( 1.2, -1.2e-3 \).
- Hexadecimal (base 16) floating point syntax. For example, \( 0xA.B, 0xA.Bp-3 \).

The syntax for these values corresponds to the syntax for VCL `FLOAT` literals in base 10 and 16 respectively. See [VCL Types](#) for details of the supported bases are 0, 10, or 16.

A base of 0 causes the base to be automatically determined from the string format. In this case, a `0x` prefix indicates hex (base 16), and other decimal (base 10).

The syntax is required to match with a corresponding prefix when an explicit base is given. That is, for base 16, the `0x` prefix must be present. The `0x` prefix must be absent.

Numbers are parsed with a rounding mode of *round to nearest with ties away from zero*.

In addition to finite values, the following special string formats are supported:

- **NaN**: NaN may be produced by the special format `NaN`. Note only one NaN representation is produced.
- **inf, +inf, -inf**: Positive and negative infinities may be produced by the special format `inf` with an optional preceding +/- sign.

The NaN and infinity special formats are case sensitive.

No whitespace is permitted by `std.strtof`.

On error, `fastly.error` is set.
Format

```plaintext
INTEGER
std.strtof(STRING s, INTEGER base)
```

Examples

```plaintext
1  if (std.strtof(req.http.PI, 10) == 3.141) {
2       set req.http.X-PI = "Close enough";
3  }
```

## std.strtol()

Converts the string `s` to an integer value. The value base must be a constant integer expression, or integer-returning function.

The following string formats are supported:

- Decimal (base 10) integer syntax. For example, `123`, `-4`.
- Hexadecimal (base 16) integer syntax. For example, `0xABC`, `-0x0`.
- Octal (base 8) integer syntax. For example, `0`, `0123`.

The syntax for integers extends the syntax for VCL `INTEGER` literals in base 10 and 16 respectively. See [VCL Types](#) for details of the `INTEGER` bases.

Supported bases are 2 - 36, inclusive, and the special value 0. For bases over 10, the alphabetic digits are case insensitive.

A base of 0 causes the base to be automatically determined from the string format. In this case, a `0x` prefix indicates hex (base 16), a prefix 8) and otherwise the base is taken as decimal (base 10).

When an explicit base is specified, the hexadecimal prefix of `0x` and the octal prefix of `0` are not required.

Whitespace and trailing characters are permitted, and have no effect on the value produced.

If the base is outside the range, or the number exceeds the range of a signed integer, `fastly.error` is set to `ERANGE`. If the number could not be converted, `fastly.error` is set to `EPARSENUM`.

On error, `fastly.error` is set.

Format

```plaintext
INTEGER
std.strtol(STRING s, INTEGER base)
```

Examples

```plaintext
1  if (std.strtol(req.http.X-HexValue, 16) == 42) {
2       set req.http.X-TheAnswer = "Found";
3  }
```

## std.suffixof()

True if the string `s` ends with the string `ends_with`. An empty string is not considered a suffix.

Returns false otherwise.

Format

```plaintext
BOOL
std.suffixof(STRING s, STRING ends_with)
```

Examples

```plaintext
1  set req.http.X-ss = std.suffixof("rectangles", "angles");
```

## std.tolower()

Changes the case of a string to lowercase. For example, `std.tolower("HELLO")` will return "hello".

Format

```plaintext
STRING
std.tolower(STRING_LIST s)
```

Examples

```plaintext
1  set beresp.http.x-nice = std.tolower("Very");
```
**std.toupper()**

Changes the case of a string to upper case. For example, `std.toupper("hello")` will return `"HELLO"`.

**Format**

```
STRING
std.toupper(STRING_LIST s)
```

**Examples**

```system
1 set beresp.http.x-scream = std.toupper("yes!");
```

**substr()**

Returns a substring of the byte string `s`, starting from the byte `offset`, of byte `length`. The substring is a copy of the original bytes.

The `length` parameter is optional. If it’s not specified, it means until the end of the string.

The `offset` parameter is zero-based. For example, `substr("abcdefg", 0, 3)` is "abc".

If the requested range is partially outside the string `s`, the returned string is truncated. For example, `substr("abcdefg", 5, 3)` is "fg".

If the requested range is completely outside the string `s`, an `unset` value is returned. For example, `substr("abc", 4, 2)` returns an `unset` value.

A negative `offset` counts backwards from the end of the string `s`. For example, `substr("abcdefg", -3, 2)` is "ef".

A negative `length` counts backwards from the end of the string `s` with the `offset` taken into account. For example, `substr("abcdefg", 1, -2)` is "de".

An `unset` value is also returned in the extreme edge cases of the `offset` or `length` causing integer overflows.

**NOTE:** `substr()` does not correctly handle UTF-8 encoded Unicode strings because byte offsets and lengths are likely to result in invalid UTF8 substr() to handle UTF-8 encoded Unicode strings.

**Format**

```
STRING
substr(STRING s, INTEGER offset [, INTEGER length])
```

**Examples**

```system
1 log "left=" substr("foobar", 0, 3)
2 log "middle=" substr("foobar", 2, 3)
3 log "right=" substr("foobar", -3)
```

**urlencode()**

Encodes a string for use in a URL. This is also known as percent-encoding. For example, `urlencode("hello world")` will return `"hello%20world"`.

**Format**

```
STRING
urlencode(STRING input)
```

**Examples**

```system
1 set req.url = req.url ?cookie= urlencode(req.http.X-Cookie);
```

**urldecode()**

Decodes a percent-encoded string. For example, `urldecode("hello%20world+!")); and `urldecode("hello%2520world+!")); will both return `"hello world+!"`.

**Format**

```
STRING
urldecode(STRING input)
```

**Examples**

```system
```

**utf8.codepoint_count()**

Returns the number of UTF-8 encoded Unicode code points in the string `s`. Returns zero if the string does not contain valid UTF-8.

**Format**

```
integer
utf8.codepoint_count(STRING s)
```

**Examples**

```system
1 set req.url = req.url ?cookie= urlencode(req.http.Cookie);
```
**STRING**

`utf8.codepoint_count(STRING s)`

**utf8.is_valid()**

Returns true if the string `s` contains valid UTF-8 and returns false if it does not contain valid UTF-8. An empty string is considered valid.

**Format**

```c
BOOL utf8.is_valid(STRING s)
```

**utf8.strpad()**

Like `std.strpad()`, except `count` gives the number of unicode code points for the output string rather than bytes.

**Errors**

This function requires the input strings `s` and `pad` to be UTF-8 encoded. If they are not, `fastly.error` will be set to `EUTF8`.

**Format**

```c
STRING utf8.strpad(STRING s, INTEGER count, STRING pad)
```

**Examples**

```c
1 utf8.strpad("abc", 7, "🌸🌼"); # gives "🌸🌼🌸🌼abc", seven code points total
2 std.strpad("abc", 7, "🌸🌼"); # gives "🌸abc" because 🌸 is four bytes
```

**utf8.substr()**

Returns a substring of the UTF-8 string `s`, starting from the Unicode code point `offset`, of Unicode code point `length`. The substring is a copy.

For example, `substr('%u{3b1}%u{3b2}%u{3b3}', 1, 1)` is "β". See `substr()` for the exact semantics of the `offset` and `length`.

If the input string is not valid UTF-8, an `unset` value is returned.

**Format**

```c
STRING utf8.substr(STRING s, INTEGER offset [, INTEGER length])
```

**Table**

Tables are declared as follows:

```c
1 table <ID> {
2   "key1": "value 1",
3   "key2": {"value 2"},
4 }
```

Either short-form or long-form strings are supported, as illustrated in the above example. The trailing comma after the final value is optional.

**Table Functions**

**table.lookup()**

Look up the key `key` in the table `<ID>`. When the key is present, its associated value will be returned. When the key is absent, the value returns `null`.

When a third `STRING` argument is provided, the lookup function behaves as it would normally, except when a key is absent, the `default` value is used.

**Format**

```c
STRING table.lookup(ID, STRING key [, STRING default])
```

**Examples**
table redirects {
  "/foo": "/bar",
  "/bat": "/baz",
}

set req.http.X-Redirect = table.lookup(redirects, req.url);
if (req.http.X-Redirect) {
  error 302 "Found";
}

---

TLS and HTTP/2

When using these variables, remember the following:
- These variables are currently only allowed to appear within the VCL hooks `vcl_recv`, `vcl_hash`, `vcl_deliver` and `vcl_log`.
- Requests made with HTTP/2 will appear in custom log as HTTP1.1 because those requests will already have been decrypted by the t
  Specifically, the `%r` variable will not accurately represent the type of HTTPX request being processed.

TLS and HTTP/2 Functions

- `h2.disable_header_compression()`

  Sets a flag to disable HTTP/2 header compression on one or many response headers to the client. Field names are case insensitive.

  Calling this function will save space in the dynamic table for other, more reusable, headers. Likewise, calling this function will not put sensiti
  by compressing them.

  By default, we disable compression for `Cookie` or `Set-Cookie` headers.

  **Format**

  `VOID`

  `h2.disable_header_compression(STRING header)`

  **Examples**

  ```
  h2.disable_header_compression("Authorization");
  h2.disable_header_compression("Authorization", "Secret");
  ```

- `h2.push()`

  Triggers an HTTP/2 server push of the asset passed into the function as the input-string.

  **Format**

  `VOID`

  `h2.push(STRING resource)`

  **Examples**

  ```
  if (fastly_info.is_h2 && req.url == "/") {
    h2.push("/assets/jquery.js");
  }
  ```

TLS and HTTP/2 Variables

- `fastly_info.h2.is_push`

  Whether or not this request was a server-initiated request generated to create an HTTP/2 Server-pushed response. Returns a boolean value

  **Type**

  `BOOL`

  **Accessibility**

  **Readable From**

  - `vcl_recv`
  - `vcl_hash`
Fastly VCL Guides

- vcl_deliver
- vcl_log

```plaintext
fastly_info.h2.stream_id
```
If the request was made over HTTP/2, the underlying HTTP/2 stream ID.

**Type**

- INTEGER

**Accessibility**

Readable From

- vcl_recv
- vcl_hash
- vcl_deliver
- vcl_log

```plaintext
fastly_info.is_h2
```
Whether or not the request was made using http2.

**Type**

- BOOL

**Accessibility**

Readable From

- vcl_recv
- vcl_hash
- vcl_deliver
- vcl_log

```plaintext
tls.client.cipher
```
The cipher suite used to secure the client TLS connection. The value returned will be consistent with the OpenSSL Name.

**Examples**

```
"ECDHE-RSA-AES128-GCM-SHA256"
```

**Type**

- STRING

**Accessibility**

Readable From

- vcl_recv
- vcl_hash
- vcl_deliver
- vcl_log

```plaintext
tls.client.ciphers_list_sha
```
A SHA-1 digest of the raw buffer containing the list of supported ciphers, represented in Base64.

**Type**

- STRING

**Accessibility**

Readable From

- vcl_recv
- vcl_hash
- vcl_deliver
- vcl_log

```plaintext
tls.client.ciphers_list_txt
```

The list of ciphers supported by the client, rendered as text, in a colon-separated list.

**Type**

**STRING**

**Accessibility**

**Readable From**

- `vcl_recv`
- `vcl_hash`
- `vcl_deliver`
- `vcl_log`

```
tls.client.ciphers_list
```

The list of ciphers supported by the client, as sent over the network, hex encoded.

**Type**

**STRING**

**Accessibility**

**Readable From**

- `vcl_recv`
- `vcl_hash`
- `vcl_deliver`
- `vcl_log`

```
tls.client.ciphers_sha
```

A SHA-1 of the cipher suite identifiers sent from the client as part of the TLS handshake, represented in Base64.

**Type**

**STRING**

**Accessibility**

**Readable From**

- `vcl_recv`
- `vcl_hash`
- `vcl_deliver`
- `vcl_log`

```
tls.client.protocol
```

The TLS protocol version this connection is speaking over. Example: "TLSv1.2"

**Type**

**STRING**

**Accessibility**

**Readable From**

- `vcl_recv`
- `vcl_hash`
- `vcl_deliver`
- `vcl_log`

```
tls.client.servername
```

The Server Name Indication (SNI) the client sent in the `ClientHello` TLS record. Returns "" if the client did not send SNI. Otherwise not sent.

**Type**

**STRING**

**Accessibility**
**tls.client.tls_exts_list_sha**

A SHA-1 digest of the TLS extensions supported by the client as little-endian, 16-bit integers, represented in Base64.

*Type*  
**STRING**

*Accessibility*

**Readable From**
- vcl_recv
- vcl_hash
- vcl_deliver
- vcl_log

**tls.client.tls_exts_list_txt**

The list of TLS extensions supported by the client, rendered as text in a colon-separated list. The value returned will be consistent with the `tls.client.tls_exts_list_sha`.

*Type*  
**STRING**

*Accessibility*

**Readable From**
- vcl_recv
- vcl_hash
- vcl_deliver
- vcl_log

**tls.client.tls_exts_list**

The list of TLS extensions supported by the client as little-endian, 16-bit, unsigned integers, hex encoded.

*Type*  
**STRING**

*Accessibility*

**Readable From**
- vcl_recv
- vcl_hash
- vcl_deliver
- vcl_log

**tls.client.tls_exts_sha**

A SHA-1 of the TLS extension identifiers sent from the client as part of the TLS handshake, represented in Base64.

*Type*  
**STRING**

*Accessibility*

**Readable From**
- vcl_recv
- vcl_hash
- vcl_deliver
- vcl_log
UUID Functions

uuid.dns()

Returns the RFC4122 identifier of DNS namespace, namely the constant "6ba7b810-9dad-11d1-80b4-00c04fd430c8".

Format

```plaintext
STRING uuid.dns()
```

Examples

```plaintext
1 declare local var.dns STRING;
2 set var.dns = uuid.version3(uuid.dns(), "www.example.com");
3 # var.dns is now "5df41881-3aed-3515-88a7-2f4a814cf09e"
```

uuid.is_valid()

Returns true if the string holds a textual representation of a valid UUID (per RFC4122). False otherwise.

Format

```plaintext
BOOL uuid.is_valid(STRING string)
```

Examples

```plaintext
1 if (uuid.is_valid(req.http.X-Unique-Id)) {
2    set beresp.http.X-Unique-Id-Valid = "yes";
3 }
```

uuid.is_version3()

Returns true if string holds a textual representation of a valid version 3 UUID. False otherwise.

Format

```plaintext
BOOL uuid.is_version3(STRING string)
```

Examples

```plaintext
1 if (uuid.is_version3(req.http.X-Unique-Id)) {
2    set beresp.http.X-Unique-Id-Valid-V3 = "yes";
3 }
```

uuid.is_version4()

Returns true if string holds a textual representation of a valid version 4 UUID. False otherwise.

Format

```plaintext
BOOL uuid.is_version4(STRING string)
```

Examples

```plaintext
1 if (uuid.is_version4(req.http.X-Unique-Id)) {
2    set beresp.http.X-Unique-Id-Valid-V4 = "yes";
3 }
```

uuid.is_version5()

Returns true if string holds a textual representation of a valid version 5 UUID. False otherwise.

Format

```plaintext
BOOL uuid.is_version5(STRING string)
```

Examples

```plaintext
1 if (uuid.is_version5(req.http.X-Unique-Id)) {
2    set beresp.http.X-Unique-Id-Valid-V5 = "yes";
3 }
```
Returns the RFC4122 identifier of ISO OID namespace, namely the constant "6ba7b812-9dad-11d1-80b4-00c04fd430c8".

**Format**

```plaintext
STRING
uuid.oid()
```

**Examples**

```
1 declare local var.oid STRING;
2 set var.oid = uuid.version3(uuid.oid(), "2.999");
3 # var.oid is now "31cb1efa-18c4-3d19-89ba-df6a74ddbd1d"
```

Returns the RFC4122 identifier of URL namespace, namely the constant "6ba7b811-9dad-11d1-80b4-00c04fd430c8".

**Format**

```plaintext
STRING
uuid.url()
```

**Examples**

```
1 declare local var.url STRING;
2 set var.url = uuid.version3(uuid.url(), "https://www.example.com/");
3 # var.url is now "7fed185f-0864-319f-875b-a3d5458e30ac"
```

**uuid.version3()**

Derives a UUID corresponding to `name` within the given `namespace` using MD5 hash function. Namespace itself is identified by a UUID. Name appropriate for selected namespace.

**NOTE:** In principle, names can be arbitrary octet strings. This implementation will, however, truncate at the first NUL byte.

**Format**

```plaintext
STRING
uuid.version3(STRING namespace, STRING name)
```

**Examples**

```
1 set req.http.X-Unique-Id = uuid.version3(uuid.dns(), "www.fastly.com");
```

**uuid.version4()**

Returns a UUID based on random number generator output.

**Format**

```plaintext
STRING
uuid.version4()
```

**Examples**

```
1 set req.http.X-Unique-Id = uuid.version4();
```

**uuid.version5()**

Derives a UUID corresponding to `name` within the given `namespace` using SHA-1 hash function. Namespace itself is identified by a UUID. Name appropriate for selected namespace.

**NOTE:** In principle, names can be arbitrary octet strings. This implementation will, however, truncate at the first NUL byte.

**Format**

```plaintext
STRING
uuid.version5(STRING namespace, STRING name)
```

**Examples**

```
1 set req.http.X-Unique-Id = uuid.version5(uuid.dns(), "www.fastly.com");
```
Returns the RFC4122 identifier of X.500 namespace, namely the constant "6ba7b812-9dad-11d1-80b4-00c04fd430c8".

Format

```plaintext
STRING
uuid.x500()
```

Examples

```plaintext
1 declare local var.x500 STRING;
2 set var.x500 = uuid.version3(uuid.x500(), "CN=Test User 1, O=Example Organization, ST=California, C=US");
3 # var.x500 is now "addf5e97-9287-3834-abfd-7edcbe7db56f"
```

---

**§ Custom VCL**

### Creating custom VCL

Fastly Varnish syntax is specifically compatible with Varnish 2.1.5. We run a custom version with added functionality and our VCL parser has mix and match Fastly VCL with your custom VCL successfully, remember the following:

- You can only restart Varnish requests three times. This limit exists to prevent infinite loops.
- VCL doesn’t take kindly to Windows newlines (line breaks). It’s best to avoid them entirely.
- It’s best to use `curl -X PURGE` to initiate purges via API. To restrict access to purging, check for the FASTLYPURGE method not the send a request to Varnish to initiate a purge, the HTTP method that you use is "PURGE", but it has already been changed to "FASTLYF VCL runs that request.
- If you override TTls with custom VCL, your default TTL set in the configuration will not be honored and the expected behavior

---

**IMPORTANT:** Personal data should not be incorporated into VCL. Our [Compliance and Law FAQ](https://docs.fastly.com/vcl/aio/) describes in detail how Fastly handle personal data.

**DANGER:** Include all of the Fastly VCL boilerplate as a template in your custom VCL file, especially the VCL macro lines (they start with `vcl`). Add your custom code *in between* the different sections as shown in the example unless you specify the VCL at that point.

**TIP:** If you use the Fastly Image Optimizer, use the [image optimization VCL boilerplate](https://docs.fastly.com/vcl/aio/) instead.

---

**Inserting custom VCL in Fastly’s VCL boilerplate**

**Custom VCL placement example**

```plaintext
1 sub vcl_miss {
2   # my custom code
3   if (req.http.User-Agent ~ "Googlebot") {
4     set req.backend = F_special_google_backend;
5   }
6   #FASTLY miss
7   return(fetch);
8 }
```

**Fastly's VCL boilerplate**

```plaintext
#TIP: If you use the Fastly Image Optimizer, use the image optimization VCL boilerplate instead.
```
sub vcl_recv {
  #FASTLY recv
  if (req.method != "HEAD" && req.method != "GET" && req.method != "FASTLYPURGE") {
    return(pass);
  }
  return(lookup);
}

sub vcl_fetch {
  #FASTLY fetch
  if ((beresp.status == 500 || beresp.status == 503) && req.restarts < 1 && req.method == "GET" || req.method == "HEAD") {
    restart;
  }
  if (req.restarts > 0) {
    set beresp.http.Fastly-Starts = req.restarts;
  }
  if (beresp.http.Set-Cookie) {
    set req.http.Fastly-Cachetype = "SETCOOKIE";
    return(pass);
  }
  if (beresp.http.Cache-Control ~ "private") {
    set req.http.Fastly-Cachetype = "PRIVATE";
    return(pass);
  }
  if (beresp.status == 500 || beresp.status == 503) {
    set beresp.ttl = 1s;
    set beresp.grace = 5s;
    return(deliver);
  }
    # keep the ttl here
  } else {
    # apply the default ttl
    set beresp.ttl = 3600s;
  }
  return(deliver);
}

sub vcl_hit {
  #FASTLY hit
  if (!obj.cacheable) {
    return(pass);
  }
  return(deliver);
}

sub vcl_miss {
  #FASTLY miss
  return(fetch);
}

sub vcl_deliver {
  #FASTLY deliver
  return(deliver);
}

sub vcl_error {
  #FASTLY error
}

sub vcl_pass {
  #FASTLY pass
}

sub vcl_log {
  #FASTLY log
}
## Uploading custom VCL

Fastly allows you to create your own Varnish Configuration Language (VCL) files with specialized configurations. By uploading custom VCL file and Fastly VCL together at the same time. Keep in mind that your custom VCL always takes precedence over VCL generated by Fastly.

### IMPORTANT: Personal data should not be incorporated into VCL. Our [Compliance and Law FAQ](https://docs.fastly.com/vcl/compliance) describes in detail how Fastly handles personal data.

## Uploading a VCL file

Follow these instructions to upload a custom VCL file:

1. Log in to the Fastly web interface and click the **Configure** link.
2. From the service menu, select the appropriate service.
3. Click the **Configuration** button and then select **Clone active**. The Domains page appears.
4. Click the **Custom VCL** tab. The Custom VCL page appears.
5. Click the **Upload a new VCL file** button. The Upload a new VCL file page appears.

### Upload a new VCL file

Our VCL tutorial will help you get started with creating VCL files.

**Name**: My custom VCL

For included files, this name must exactly match the include statement in the main VCL file.

**Config file**: UPLOAD FILE custom.vcl

6. In the **Name** field, enter the name of the VCL file. For included files, this name must match the include statement in the main VCL file. [additional VCL configurations](https://docs.fastly.com/vcl) for more information.

7. Click **Upload file** and select a file to upload. The name of the uploaded file appears next to the button.

### IMPORTANT: Don’t upload generated VCL that you’ve downloaded from the Fastly web interface. Instead, edit and then upload boilerplate to avoid errors.

8. Click the **Create** button. The VCL file appears in the Varnish Configurations area.

9. Click the **Activate** button to deploy your configuration changes.

## Editing a VCL file

To edit an existing VCL file, follow these instructions:

1. Log in to the Fastly web interface and click the **Configure** link.
2. From the service menu, select the appropriate service.
3. Click the **Configuration** button and then select **Clone active**. The Domains page appears.
4. Click the **Custom VCL** tab. The Custom VCL page appears.
5. In the Varnish Configurations area, click the VCL file you want to edit. The Edit an existing VCL file page appears.
6. In the **Name** field, optionally enter a new name of the VCL file.
7. Click the **Download** link to download the appropriate file.
8. Make the necessary changes to your file and save them.
9. Click the **Replace file** button and select the file you updated. The selected file replaces the current VCL file and the file name appears.
10. Click the **Update** button to update the VCL file in the Fastly application.
11. Click the **Activate** button to deploy your configuration changes.

### Including additional VCL configurations

You can apply additional VCL files along with your main VCL by including their file names in the main VCL file using the syntax `include "VC`

For example, if you’ve created an included VCL object called "ACL" (to use an access control list for code manageability) and the file is named `ACL.vcl` the VCL configuration file would need to contain this line:

```
include "ACL"
```

### Previewing and testing VCL

Any time you upload VCL files you can preview and test the VCL prior to activating a new version of your service.

#### Previewing VCL before activation

To preview VCL prior to activating a service version:

1. Log in to the Fastly web interface and click the **Configure** link.
2. From the service menu, select the appropriate service.
3. Click the **Configuration** button and then select **Clone active**. The Domains page appears.
4. Click the **Show VCL** link.

```
www.example.com  Switch services  Service ID: ABCDI
```

```
Version 53 (draft)  Switch versions  Clone  Diff versions
```

The VCL preview page appears.

### Testing VCL configurations

You don’t need a second account to test your VCL configurations. We recommend adding a new service within your existing account that’s testing. A name like "QA" or "testing" or "staging" makes distinguishing between services much easier.
Once created, simply point your testing service to your testing or QA environment. Edit your Fastly configurations for the testing service as if production. Preview your VCL, test things out, and tweak them to get them perfect.

When your testing is complete, make the same changes in your production service that you made to your testing service. If you are using curl file to the production service you'll be using.

§ VCL Snippets

About VCL Snippets

VCL Snippets are short blocks of VCL logic that can be included directly in your service configurations. They're ideal for adding small sections of VCL code whenever you need more complex, specialized configurations that sometimes require custom VCL. Fastly supports two types of VCL Snippets:

- **Regular VCL Snippets** get created as you create versions of your Fastly configurations. They belong to a specific service, and any modifications made to them are locked and deployed when you deploy a new version of that service. You can treat regular snippets like any other Fastly object to clone them and deploy them with a service until you specifically delete them. You can create regular snippets using either the web interface or command line tools.

- **Dynamic VCL Snippets** can be modified and deployed any time they're changed. Because they are versionless objects (much like Edge Dictionaries or ACLs at the edge), dynamic snippets can be modified independently from service changes. This means you can modify snippet code rapidly without deploying a service version that may not be ready for production. You can only create dynamic snippets via the API.

Limitations of VCL Snippets

- Snippets are limited to 1MB in size by default. If you need to store snippets larger than the limit, contact support@fastly.com.
- Snippets don't currently support conditions created through the web interface. You can, however, use `if` statements in snippet code.
- Snippets cannot currently be shared between services.

Using dynamic VCL Snippets

Dynamic VCL Snippets are one of two types of snippets that allow you to insert small sections of VCL logic into your service configuration via VCL (though you can still include snippets in custom VCL when necessary).

You can only create dynamic snippets via the API. Because they are versionless objects (much like Edge Dictionaries or ACLs at the edge), they can be modified independently from changes to your Fastly service. This means you can modify snippet code rapidly without deploying a service version that may not be ready for production.

Creating and using a dynamic VCL Snippet

Using the cURL command line tool, make the following API call in a terminal application:

```bash
1  curl -X POST -s https://api.fastly.com/service/<Service ID>/version/<Editable Version #>/snippet -H "Fastly-Key:FASTLY_API_key" --data "name=my_dynamic_snippet_name&type=recv&dynamic=1&content=if ( req.url ) {
  set t-header = "true";
}"
```

Fastly returns a JSON response that looks like this:

```json
1  {  
2   "service_id": "<Service Id>",  
3   "version": "<Editable Version>",  
4   "name": "my_dynamic_snippet_name",  
5   "type": "recv",  
6   "priority": 100,  
7   "dynamic": 1,  
8   "content": null,  
9   "id": "decafbad12345",  
10  "created_at": "2016-09-09T20:34:51+00:00",  
11  "updated_at": "2016-09-09T20:34:51+00:00",  
12  "deleted_at": null  
13  }
```

**NOTE:** The returned JSON includes `"content": null`. This happens because the content is stored in a separate, unversioned object

Viewing dynamic VCL Snippets in the web interface

You can view a list of dynamic VCL snippets. You can also view just the source of a specific snippet or a specific snippet’s location in generation.
Viewing a list of dynamic VCL Snippets

To view the entire list of a service’s dynamic VCL Snippets directly in the web interface:

1. Log in to the Fastly web interface and click the Configure link.
2. From the service menu, select the appropriate service.
3. Click the VCL Snippets link. The VCL Snippets page appears listing all dynamic VCL Snippets for your service in the Dynamic snippet

Dynamic snippets

These are the dynamic snippets currently in use. You can only edit them via the API because they are not versioned.

<table>
<thead>
<tr>
<th>Snippet Description</th>
<th>View source</th>
<th>Show in generated VCL</th>
</tr>
</thead>
<tbody>
<tr>
<td>My snippet that is dynamic</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Priority: 10</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type: init</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

| My other snippet that is dynamic     |             |                       |
| Priority: 10                         |             |                       |
| Type: init                           |             |                       |

| My third snippet that is dynamic     |             |                       |
| Priority: 10                         |             |                       |
| Type: init                           |             |                       |

Viewing the source of a specific snippet

You can view just the source of a specific snippet:

1. Log in to the Fastly web interface and click the Configure link.
2. From the service menu, select the appropriate service.
3. Click the VCL Snippets link. The VCL Snippets page appears.
4. Click the View Source link to the right of the name of the snippet. A view source window appears.

Viewing the location of a specific snippet in generated VCL

You can view a specific snippet’s location in generated VCL:

1. Log in to the Fastly web interface and click the Configure link.
2. From the service menu, select the appropriate service.
3. Click the VCL Snippets link. The VCL Snippets page appears.
4. Click the Show in Generated VCL link to the right of the name of the snippet. The Generated VCL window appears.

Fetching a list of all dynamic VCL Snippets

To list all dynamic VCL Snippets attached to a service, make the following API call in a terminal application:

```
1 curl -X GET -s https://api.fastly.com/service/<Service ID>/version/<Editable Version #>/snippet -H "Fastly-Key:FASTLY_API_TOKEN"
```

Fetching an individual dynamic VCL Snippet

To fetch an individual snippet, make the following API call in a terminal application:

```
1 curl -X GET -s https://api.fastly.com/service/<Service ID>/snippet/<my_dynamic_snippet_id> -H "Fastly-Key:FASTLY_API_TOKEN"
```

Unlike fetching regular VCL Snippets, you do not include the version in the URL and you must use the ID returned when the snippet was created.

Updating an existing dynamic VCL Snippet

To update an individual snippet, make the following API call in a terminal application:

```
1 curl -X PUT -s https://api.fastly.com/service/<Service ID>/snippet/<my_dynamic_snippet_id> -H "Fastly-Key:FASTLY_API_TOKEN" cation/x-www-form-urlencoded --data $'content=if ( req.url ) {
 set req.http.my-snippet-test-header = "affirmative";
}
```

Deleting an existing dynamic VCL Snippet

To delete an individual snippet, make the following API call in a terminal application:
Including dynamic snippets in custom VCL

By specifying a location of `none` for the `type` parameter, snippets will not be rendered in VCL. This allows you to include snippets in custom syntax:

```vcl
#include "snippet::<snippet name>"
```

The same VCL Snippet can be included in custom VCL in as many places as needed.

Example use: blocking site scrapers

Say you wanted to implement some pattern matching against incoming requests to block someone trying to scrape your site. Say also that that looks at all incoming requests and generates a set of rules that can identify scrapers using a combination of the incoming IP address, if they're trying to fetch. Finally, say that the system updates the rules every 20 minutes.

If, during system updates, your colleagues are also making changes to the rest of your Fastly configuration, you probably don't want the system to use the latest version of the service since it might be untested. Instead you could generate the rules as a Dynamic VCL Snippet. Whenever the system updates the rules, the logic remains the same as the currently deployed version and only your rules are modified.

### Using regular VCL Snippets

Regular VCL Snippets are one of two types of snippets that allow you to insert small sections of VCL logic into your service configuration (though you can still include snippets in custom VCL when necessary).

Unlike dynamic snippets, regular snippets can be created via the web interface or via the API. They are considered "versioned" objects. The service and any modifications you make to the snippet are locked and deployed when you deploy a new version of that service. We continue to lock them with a service until you specifically delete them.

Creating a regular VCL Snippet

You can create regular VCL Snippets via the web interface or via the API.

**Via the web interface**

To create a regular VCL Snippet via the web interface:

1. Log in to the Fastly web interface and click the Configure link.
2. From the service menu, select the appropriate service.
3. Click the VCL Snippets link. The VCL Snippets page appears.
4. Click Create Snippet. The Create a VCL snippet page appears.

---

### Create a VCLSnippet

**VCL snippet gi**

**Name**

**Type (placement of the snippet)**

- [ ] init - inserts the snippets above all access control lists, tables)
- [x] within subroutine - inserts the snippet boilerplate code and preceeding ar
5. In the **Name** field, type an appropriate name (for example, *Example Snippet*).

6. Using the **Type** controls, select the location in which the snippet should be placed as follows:
   - Select **init** to insert it above all subroutines in your VCL.
   - Select **within subroutine** to insert it within a specific subroutine and then select the specific subroutine from the **Select subroutine** drop-down menu.
   - Select **none (advanced)** to insert it manually. See [Including regular snippets in custom VCL](https://docs.fastly.com/vcl/aio/878/985) for the additional manual insertion requirements.

7. In the **VCL** field, type the snippet of VCL logic to be inserted for your service version.
8. Click **Create** to create the snippet.

---

**Via the API**

To create a regular VCL Snippet via the API, make the following API call using the cURL command line tool in a terminal application:

```
$ curl -X POST -s https://api.fastly.com/service/<Service ID>/version/<Editable Version #>/snippet -H "Fastly-Key:FASTLY_API_ ` -H 'Content-Type: application/x-www-form-urlencoded' --data $'name=my_regular_snippet&type=recv&dynamic=0&content=if ( re p.my-snippet-test-header = "true";\n);
```

Fastly returns a JSON response that looks like this:

```json
{
  "service_id": "<Service Id>",
  "version": "<Editable Version>",
  "name": "my_regular_snippet",
  "type": "recv",
  "content": "if ( req.url ) {\n    set req.http.my-snippet-test-header = "true";\n  }",
  "priority": 100,
  "dynamic": 0,
  "id": "56789exampleid",
  "created_at": "2016-09-09T20:34:51+00:00",
  "updated_at": "2016-09-09T20:34:51+00:00",
  "deleted_at": null
}
```

**NOTE:** When regular VCL snippets get created, an `id` field will be returned that isn't used. The field only applies to dynamic VCL Snippets. The returned JSON includes a populated `content` field because the snippet content is stored in a versioned object.

---

**Viewing regular VCL Snippets in the web interface**

You can view a list of regular VCL snippets. You can also view just the source of a specific snippet or a specific snippet's location in generated VCL.

**Viewing a list of regular VCL Snippets**

To view the entire list of a service's regular VCL Snippets directly in the web interface:

1. Log in to the Fastly web interface and click the **Configure** link.
2. From the service menu, select the appropriate service.
3. Click the **VCL Snippets** link. The VCL Snippets page appears listing all available VCL snippets for your service.

---

**Viewing the source of a specific snippet**

You can view just the source of a specific snippet:

1. Log in to the Fastly web interface and click the **Configure** link.
2. From the service menu, select the appropriate service.
3. Click the **VCL Snippets** link. The VCL Snippets page appears.

4. Click the **View Source** link to the right of the name of the snippet. A view source window appears.

**Viewing the location of a specific snippet in generated VCL**

You can view a specific snippet’s location in generated VCL:

1. Log in to the Fastly web interface and click the **Configure** link.
2. From the service menu, select the appropriate service.
3. Click the **VCL Snippets** link. The VCL Snippets page appears.
4. Click the **Show in Generated VCL** link to the right of the name of the snippet. The Generated VCL window appears.

**Fetching regular VCL Snippets via the API**

You can fetch regular VCL Snippets for a particular service via the API either singly or all at once.

**Fetching an individual regular VCL Snippet**

To fetch an individual snippet, make the following API call in a terminal application:

```bash
1 curl -X GET -s https://api.fastly.com/service/<Service ID>/version/<Editable Version #>/snippet/<Snippet Name e.g my_regular
```

Unlike fetching dynamic VCL Snippets you include the version in the URL and you must use the name of the snippet, not the ID.

**Fetching a list of regular VCL Snippets**

To list all regular VCL Snippets attached to a service, make the following API call in a terminal application:

```bash
1 curl -X GET -s https://api.fastly.com/service/<Service ID>/version/<Editable Version #>/snippet/ -H "Fastly-Key:FASTLY_API
```

**Updating an existing regular VCL Snippet**

You can update existing regular VCL Snippets via the web interface or via the API.

**Via the web interface**

To update an individual snippet via the web interface:

1. Log in to the Fastly web interface and click the **Configure** link.
2. From the service menu, select the appropriate service.
3. Click the **VCL Snippets** link. The VCL Snippets page appears.
4. Click the pencil icon next to the name of the snippet to be updated.

The Edit snippet page appears.
5. Update the snippet’s settings or VCL as appropriate.

6. Click **Update** to save your changes.

### Via the API

To update an individual snippet via the API, make the following API call in a terminal application:

```bash
curl -X PUT -s https://api.fastly.com/service/<Service ID>/version/<Editable Version #>/snippet/<Snippet Name e.g my_regular:FASTLY_API_TOKEN" -H 'Content-Type: application/x-www-form-urlencoded' --data $'content=if ( req.url ) {
    set req.http.method = "affirmative";
};'
```

### Deleting an existing regular VCL Snippet

You can update existing regular VCL Snippets via the web interface or via the API.

#### Via the web interface

1. Log in to the Fastly web interface and click the **Configure** link.
2. From the service menu, select the appropriate service.
3. Click the **VCL Snippets** link. The VCL Snippets page appears.
4. Click the trashcan icon to the right of the name of the snippet to be updated.
A confirmation window appears.

Are you sure you want to delete "Example Snippet" snippet?

CONFIRM AND DELETE

5. Click **Confirm and Delete**.

Via the API

To delete an individual snippet via the API, make the following API call in a terminal application:

```
1 curl -X DELETE -s https://api.fastly.com/service/<Service ID>/version/<Editable Version #>/snippet/<Snippet Name e.g my_reg
2 -Key:FASTLY_API_TOKEN
```

Including regular snippets in custom VCL

Snippets will not be rendered in VCL if you select **none (advanced)** for the snippet type in the web interface or specify a location of **none**! in the API. This allows you to manually include snippets in custom VCL using the following syntax:

```
1 include "snippet::<snippet name>"
```

The same VCL Snippet can be included in custom VCL in as many places as needed.

Example use: location-based redirection

Say that you work at a large content publisher and you want to redirect users to different editions of your publication depending on which cc they come from. Say also that you want the ability to override the edition you deliver to them based on a cookie.

Using regular VCL snippets, you could add a new object with the relevant VCL as follows:

```
3   set req.backend = F_US;
4 } elseif (req.http.Cookie:edition == "Europe" || server.region ~ "^EU-" ) {
5   set req.http.Edition = "EU";
6   set req.backend = F_European;
7 } else {
8   set req.http.Edition = "INT";
9   set req.backend = F_International;
10 }
```

This would create an Edition header in VCL, but allow you to override it by setting a condition. You would add the Edition header into Vary at condition (e.g., !reg.url) to your other backends to ensure the correct edition of your publication gets delivered (Remember: VCL Snippet backends are set.)

§ VCL Reference
Functions

These VCL functions are supported by Fastly.

Content negotiation

Functions for selecting a response from common content negotiation request headers.

- `accept.charset_lookup()` — Selects the best match from a string in the format of an `Accept-Charset` header’s value in the listed char algorithm described in Section 5.3.3 of RFC 7231.

- `accept.encoding_lookup()` — Selects the best match from a string in the format of an `Accept-Encoding` header’s value in the listed cc algorithm described in Section 5.3.3 of RFC 7231.

- `accept.language_filter_basic()` — Similar to `accept.language_lookup()`, this function selects the best matches from a string in the fo Language header’s value in the listed languages, using the algorithm described in RFC 4647, Section 3.3.1.

- `accept.language_lookup()` — Selects the best match from a string in the format of an `Accept-Language` header’s value in the listed lar algorithm described in RFC 4647, Section 3.4.

- `accept.media_lookup()` — Selects the best match from a string in the format of an `Accept` header’s value in the listed media types, us in Section 5.3.2 of RFC 7231.

Cryptographic

Fastly provides several functions in VCL for cryptographic- and hashing-related purposes. It is based very heavily on Kristian Lyngstøl’s `digest` (which means you can also refer to that documentation for more detail).

- `digest.aws4_hmac()` — Returns an AWSv4 message authentication code based on the supplied key and string.

- `digest.base64_decode()` — Returns the Base64 decoding of the input string, as specified by RFC 4648.

- `digest.base64()` — Returns the Base64 encoding of the input string, as specified by RFC 4648.

- `digest.base64url_decode()` — Returns the Base64 decoding with URL and filename safe alphabet decoding of the input string, as spec

- `digest.base64url_nopad_decode()` — Returns the Base64 decoding with URL and filename safe alphabet decoding of the input string, without padding (=).

- `digest.base64url_nopad()` — Returns the Base64 encoding with URL and filename safe alphabet encoding of the input string, as specif padding (=).

- `digest.base64url()` — Returns the Base64 encoding with URL and filename safe alphabet of the input string, as specified by RFC 4648.

- `digest.hash_crc32()` — Calculates the 32-bit Cyclic Redundancy Checksum with reversed bit ordering of a string, like that used by bzip

- `digest.hash_crc32b()` — Calculates the 32-bit Cyclic Redundancy Checksum of a string, as specified by ISO/IEC 13239:2002 and sect recommendation V.42 and used by Ethernet (IEEE 802.3), V.42, FDDI, gzip, zip, and PNG.

- `digest.hash_md5()` — Use the MD5 hash.

- `digest.hash_sha1()` — Use the SHA-1 hash.

- `digest.hash_sha256()` — Use the SHA-256 hash.

- `digest.hash_sha384()` — Use the SHA-384 hash.

- `digest.hash_sha512()` — Use the SHA-512 hash.

- `digest.hmac_md5_base64()` — Hash-based message authentication code using MD5.

- `digest.hmac_md5()` — Hash-based message authentication code using MD5.

- `digest.hmac_sha1_base64()` — Hash-based message authentication code using SHA-1.

- `digest.hmac_sha1()` — Hash-based message authentication code using SHA-1.

- `digest.hmac_sha256_base64()` — Hash-based message authentication code using SHA-256.

- `digest.hmac_sha256()` — Hash-based message authentication code using SHA-256.

- `digest.hmac_sha512_base64()` — Hash-based message authentication code using SHA-512.

- `digest.rsa_verify()` — A boolean function that returns true if the RSA signature of payload using public_key matches digest.

- `digest.secure_is_equal()` — A boolean function that returns true if s1 and s2 are equal.

- `digest.time_hmac_md5()` — Returns a time-based one-time password using MD5 based upon the current time.

- `digest.time_hmac_sha1()` — Returns a time-based one-time password using SHA-1 based upon the current time.
*digest.time_hmac_sha256()* — Returns a time-based one-time password with SHA-256 based upon the current time.

*digest.time_hmac_sha512()* — Returns a time-based one-time password with SHA-512 based upon the current time.

**Date and time**

By default VCL includes the `now` variable, which provides the current time (for example, *Mon, 02 Jan 2006 22:04:05 GMT*). Fastly adds several functions that allow more flexibility when dealing with dates and times.

- `parse_time_delta()` — Parses a string representing a time delta and returns an integer number of seconds.
- `std.integer2time()` — Converts an integer, representing seconds since the UNIX Epoch, to a time variable.
- `strftime()` — Formats a time to a string.
- `time.add()` — Adds a relative time to a time.
- `time.hex_to_time()` — This specialized function takes a hexadecimal string value, divides by `divisor` and interprets the result as seconds.
- `time.is_after()` — Returns true if `t1` is after `t2`.
- `time.is_before()` — Returns true if `t1` is before `t2`.
- `time.is_direction()` — Returns true if `t1` is before or after `t2`.
- `time.is_equal()` — Returns true if `t1` is equal to `t2`.
- `time.is_not_equal()` — Returns true if `t1` is not equal to `t2`.
- `time.sub()` — Subtracts a relative time from a time.

**Floating point classification**

Floating point classification functions.

- `math.is_finite()` — Determines whether a floating point value is finite.
- `math.is_infinite()` — Determines whether a floating point value is an infinity.
- `math.is_nan()` — Determines whether a floating point value is NaN (Not a Number).
- `math.is_normal()` — Determines whether a floating point value is normal.
- `math.is_subnormal()` — Determines whether a floating point value is subnormal.

**Math rounding**

Rounding of numbers.

- `math.ceil()` — Computes the smallest integer value greater than or equal to the given value.
- `math.floor()` — Computes the largest integer value less than or equal to the given value.
- `math.round()` — Rounds `x` to the nearest integer, with ties away from zero (*commercial rounding*).
- `math.roundeven()` — Rounds `x` to nearest, ties to even (*bankers' rounding*).
- `math.roundhalfdown()` — Rounds to nearest, ties towards negative infinity (*half down*).
- `math.roundhalfup()` — Rounds to nearest, ties towards positive infinity (*half up*).
- `math.trunc()` — Truncates `x` to an integer value less than or equal in absolute value.

**Math trigonometric**

Trigonometric functions.

- `math.acos()` — Computes the principal value of the arc cosine of its argument `x`.
- `math.acosh()` — Computes the inverse hyperbolic cosine of its argument `x`.
- `math.asin()` — Computes the principal value of the arc sine of the argument `x`.
- `math.asinh()` — Computes the inverse hyperbolic sine of its argument `x`.
- `math.atan()` — Computes the principal value of the arc tangent of its argument `x`.
- `math.atan2()` — Computes the principal value of the arc tangent of `y/x`, using the signs of both arguments to determine the quadrant of the result.
- `math.atanh()` — Computes the inverse hyperbolic tangent of its argument `x`.
- `math.cos()` — Computes the cosine of its argument `x`, measured in radians.
- `math.cosh()` — Computes the hyperbolic cosine of its argument `x`.
- `math.sin()` — Computes the sine of its argument `x`, measured in radians.
- `math.sinh()` — Computes the hyperbolic sine of its argument `x`.
- `math.sqrt()` — Computes the square root of its argument `x`.
- `math.tan()` — Computes the tangent of its argument `x`, measured in radians.
- `math.tanh()` — Computes the hyperbolic tangent of its argument `x`.
**Miscellaneous**

Fastly has added several miscellaneous features to Varnish that don’t easily fit into specific categories.

- `addr.extract_bits()` — Extracts bit_count bits (at most 32) starting with the bit number start_bit from the given IPv4 or IPv6 address form of a non-negative integer.
- `addr.is_ipv4()` — Returns true if the address family of the given address is IPv4.
- `addr.is_ipv6()` — Returns true if the address family of the given address is IPv6.
- `http_status_matches()` — Determines whether the HTTP status matches or does not match any of the statuses in the supplied fmt string.
- `if()` — Implements a ternary operator for strings; if the expression is true, it returns value-when-true; if the expression is false, it returns value-when-false.
- `setcookie.get_value_by_name()` — Returns a value associated with the cookie_name in the Set-Cookie header contained in the HTTP where.
- `std.collect()` — Combines multiple instances of the same header into one.
- `subfield()` — Provides a means to access subfields from a header like Cache-Control, Cookie, and Edge-Control or individual parameters.

**Query string manipulation**

Fastly provides a number of extensions to VCL, including several functions for query-string manipulation based on Dridi Boukelmoune’s vmo libraries.

- `boltsort.sort()` — Alias of `querystring.sort()`.
- `querystring.add()` — Returns the given URL with the given parameter name and value appended to the end of the query string.
- `querystring.clean()` — Returns the given URL without empty parameters.
- `querystring.filter_except()` — Returns the given URL but only keeps the listed parameters.
- `querystring.filter()` — Returns the given URL without the listed parameters.
- `querystring.globfilter_except()` — Returns the given URL but only keeps the parameters matching a glob.
- `querystring.globfilter()` — Returns the given URL without the parameters matching a glob.
- `querystring.regfilter_except()` — Returns the given URL but only keeps the parameters matching a regular expression.
- `querystring.regfilter()` — Returns the given URL without the parameters matching a regular expression.
- `querystring.remove()` — Returns the given URL with its query-string removed.
- `querystring.set()` — Returns the given URL with the given parameter name set to the given value, replacing the original value and removing any other occurrences.
- `querystring.sort()` — Returns the given URL with its query-string sorted.

**Randomness**

Fastly exposes a number of functions that support the insertion of random strings, content cookies, and decisions into requests.

- `randombool_seeded()` — Identical to `randombool`, except takes an additional parameter, which is used to seed the random number generator.
- `randombool()` — Returns a random, boolean value.
- `randomint_seeded()` — Identical to `randomint`, except takes an additional parameter used to seed the random number generator.
- `randomint()` — Returns a random integer value between from and to, inclusive.
- `randomstr()` — Returns a random string of length len containing characters from the supplied string.

**String manipulation**

These functions provide various manipulation for strings containing arbitrary text content.

- `cstr_escape()` — Escapes bytes from a string using C-style escape sequences.
- `json.escape()` — Escapes characters of a UTF-8 encoded Unicode string using JSON-style escape sequences.
- `regsub()` — Replaces the first occurrence of pattern, which is a Perl-compatible regular expression, in input with replacement.
- `regsuball()` — Replaces all occurrences of pattern, which may be a Perl-compatible regular expression, in input with replacement.
- `std.anystr2ip()` — Converts the string addr to an IP address (IPv4 or IPv6).
- `std.atof()` — Takes a string (which represents a float) as an argument and returns its value.
- `std.atoi()` — Takes a string (which represents an integer) as an argument and returns its value.
- `std.ip()` — An alias of std.str2ip().
- `std.ip2str()` — Converts the IP address (v4 or v6) to a string.
- `std.prefixof()` — True if the string `s` begins with the string `begins_with`.
- `std.str2ip()` — Converts the string representation of an IP address (IPv4 or IPv6) into an IP type.
- `std.strlen()` — Returns the length of the string.
- `std.strpad()` — This function constructs a string containing the input string `s` padded out with `pad` to produce a string of the given `wi`.
- `std.strep()` — Repeats the given string `n` times.
- `std.strrev()` — Reverses the given string.
- `std.strstr()` — Returns the part of `haystack` string starting from and including the first occurrence of `needle` until the end of `haystack`.
- `std.strtof()` — Converts the string `s` to a float value with the given base `base`.
- `std.strtol()` — Converts the string `s` to an integer value.
- `std.suffixof()` — True if the string `s` ends with the string `ends_with`.
- `std.tolower()` — Changes the case of a string to lowercase.
- `std.toupper()` — Changes the case of a string to upper case.
- `strpad()` — Returns a substring of the byte string `s`, starting from the byte `offset`, of byte `length`.
- `urldecode()` — Decodes a percent-encoded string.
- `urlencode()` — Encodes a string for use in a URL.
- `utf8.codepoint_count()` — Returns the number of UTF-8 encoded Unicode code points in the string `s`.
- `utf8.is_valid()` — Returns true if the string `s` contains valid UTF-8 and returns false if it does not contain valid UTF-8.
- `utf8.strpad()` — Like `std.strpad()`, except `count` gives the number of unicode code points for the output string rather than bytes.
- `utf8.substr()` — Returns a substring of the UTF-8 string `s`, starting from the Unicode code point `offset`, of Unicode code point `length`.

**Table**

Tables provide a means to declare a constant dictionary and to efficiently look up values in the dictionary.

- `table.lookup()` — Look up the key `key` in the table `ID`.

**TLS and HTTP/2**

Fastly has added several variables that expose information about the TLS and HTTP/2 attributes of a request.

- `h2.disable_header_compression()` — Sets a flag to disable HTTP/2 header compression on one or many response headers to the client.
- `h2.push()` — Triggers an HTTP/2 server push of the asset passed into the function as the input-string.

**UUID**

The universally unique identifier (UUID) module provides interfaces for generating and validating unique identifiers as defined by RFC4122. V on current time and host identity, are currently not supported.

- `uuid.dns()` — Returns the RFC4122 identifier of DNS namespace, namely the constant "6ba7b810-9dad-11d1-80b4-00c04fd430c8".
- `uuid.is_valid()` — Returns true if the string `s` holds a textual representation of a valid UUID (per RFC4122).
- `uuid.is_version3()` — Returns true if string holds a textual representation of a valid version 3 UUID.
- `uuid.is_version4()` — Returns true if string holds a textual representation of a valid version 4 UUID.
- `uuid.is_version5()` — Returns true if string holds a textual representation of a valid version 5 UUID.
- `uuid.oid()` — Returns the RFC4122 identifier of ISO OID namespace, namely the constant "6ba7b812-9dad-11d1-80b4-00c04fd430c8".
- `uuid.url()` — Returns the RFC4122 identifier of URL namespace, namely the constant "6ba7b811-9dad-11d1-80b4-00c04fd430c8".
- `uuid.version3()` — Derives a UUID corresponding to `name` within the given `namespace` using MD5 hash function.
- `uuid.version4()` — Returns a UUID based on random number generator output.
- `uuid.version5()` — Derives a UUID corresponding to `name` within the given `namespace` using SHA-1 hash function.
- `uuid.x500()` — Returns the RFC4122 identifier of X.500 namespace, namely the constant "6ba7b812-9dad-11d1-80b4-00c04fd430c8".

**Variables**

These VCL variables are supported by Fastly.

**Date and time**
By default VCL includes the `now` variable, which provides the current time (for example, Mon, 02 Jan 2006 22:04:05 GMT). Fastly adds several functions that allow more flexibility when dealing with dates and times.

- `now.sec` — Like the `now` variable, but in seconds since the UNIX Epoch.
- `now` — The current time in RFC 1123 format (e.g., Mon, 02 Jan 2006 22:04:05 GMT).
- `time.elapsed.msec_frac` — The time that has elapsed in milliseconds since the request started.
- `time.elapsed.msec` — The time since the request start in milliseconds.
- `time.elapsed.sec` — The time since the request start in seconds.
- `time.elapsed.usec_frac` — The time the request started in microseconds since the last whole second.
- `time.elapsed.usec` — The time since the request start in microseconds.
- `time.elapsed` — The time since the request started.
- `time.end.msec_frac` — The time the request started in milliseconds since the last whole second.
- `time.end.msec` — The time the request ended in milliseconds since the UNIX Epoch.
- `time.end.sec` — The time the request ended in seconds since the UNIX Epoch.
- `time.end.usec_frac` — The time the request started in microseconds since the last whole second.
- `time.end.usec` — The time the request ended in microseconds since the UNIX Epoch.
- `time.end` — The time the request ended, using RFC 1123 format (e.g., Mon, 02 Jan 2006 22:04:05 GMT).
- `time.start.msec_frac` — The time the request started in milliseconds since the last whole second, after TLS termination.
- `time.start.msec` — The time the request started in milliseconds since the UNIX Epoch, after TLS termination.
- `time.start.sec` — The time the request started in seconds since the UNIX Epoch, after TLS termination.
- `time.start.usec_frac` — The time the request started in microseconds since the last whole second, after TLS termination.
- `time.start.usec` — The time the request started in microseconds since the UNIX Epoch, after TLS termination.
- `time.start` — The time the request started, after TLS termination, using RFC 1123 format (e.g., Mon, 02 Jan 2006 22:04:05 GMT).
- `time.to_first_byte` — The time interval since the request started up to the point before the `vcl_deliver` function ran.

**Edge Side Includes (ESI)**

Fastly exposes tools to allow you to track a request that has ESI.

- `req.esi` — Whether or not to disable or enable ESI processing during this request.
- `req.topurl` — In an ESI subrequest, contains the URL of the top-level request.

**Geolocation**

Fastly exposes a number of geographic variables for you to take advantage of inside VCL for both IPv4 and IPv6 client IPs.

- `client.as.name` — The name of the organization associated with `client.as.number`.
- `client.as.number` — Autonomous system (AS) number.
- `client.geo.area_code` — The telephone area code associated with the IP address.
- `client.geo.city.ascii` — City or town name, encoded using ASCII encoding.
- `client.geo.city.latin1` — City or town name, encoded using Latin-1 encoding.
- `client.geo.city.utf8` — City or town name, encoded using UTF-8 encoding.
- `client.geo.conn_speed` — Connection speed.
- `client.geo.continent_code` — Two-letter code representing the continent.
- `client.geo.country_code` — A two-character ISO 3166-1 country code for the country associated with the IP address.
- `client.geo.country_code3` — A three-character ISO 3166-1 alpha-3 country code for the country associated with the IP address.
- `client.geo.country_name.ascii` — Country name, encoded using ASCII encoding.
- `client.geo.country_name.latin1` — Country name, encoded using Latin-1 encoding.
- `client.geo.country_name.utf8` — Country name, encoded using UTF-8 encoding.
- `client.geo.country_name` — Alias of `client.geo.country_name.ascii`.
- `client.geo.gmt_offset` — Time zone offset from coordinated universal time (UTC) for `client.geo.city`.
- `client.geo.ip_override` — Override the IP address for geolocation data.
- `client.geo.latitude` — Latitude, in units of degrees from the equator.
- `client.geo.longitude` — Longitude, in units of degrees from the IERS Reference Meridian.
- `client.geo.metro_code` — Metro code.
- `client.geo.postal_code` — The postal code associated with the IP address.
- `client.geo.region.ascii` — ISO 3166-2 country subdivision code.
- `client.geo.region.latin1` — Region code, encoded using Latin-1 encoding.
- `client.geo.region.utf8` — Region code, encoded using UTF-8 encoding.

### Math constants and limits

Features that support various math constants and limits.

- `math.1_PI` — The value of the reciprocal of `math.PI` (1/Pi).
- `math.2_PI` — The value of two times the reciprocal of `math.PI` (2/Pi).
- `math.2_SQRTPI` — The value of two times the reciprocal of the square root of `math.PI` (2/sqrt(Pi)).
- `math.2PI` — The value of `math.PI` multiplied by two (Tau).
- `math.E` — The value of the base of natural logarithms (e).
- `math.FLOAT_DIG` — Number of decimal digits that can be stored without loss in the `FLOAT` type.
- `math.FLOAT_EPSILON` — Minimum positive difference from 1.0 for the `FLOAT` type.
- `math.FLOAT_MANT_DIG` — Number of hexadecimal digits stored for the significand in the `FLOAT` type.
- `math.FLOAT_MAX_10_EXP` — Maximum value in base 10 of the exponent part of the `FLOAT` type.
- `math.FLOAT_MAX_EXP` — Maximum value in base 2 of the exponent part of the `FLOAT` type.
- `math.FLOAT_MAX` — Maximum finite value for the `FLOAT` type.
- `math.FLOAT_MIN_10_EXP` — Minimum value in base 10 of the exponent part of the `FLOAT` type.
- `math.FLOAT_MIN_EXP` — Minimum value in base 2 of the exponent part of the `FLOAT` type.
- `math.FLOAT_MIN` — Minimum finite value for the `FLOAT` type.
- `math.INTEGER_BIT` — Number of bits in the `INTEGER` type.
- `math.INTEGER_MAX` — Maximum value for the `INTEGER` type.
- `math.INTEGER_MIN` — Minimum value for the `INTEGER` type.
- `math.LN10` — The value of the natural logarithm of 10 (log_e 10).
- `math.LN2` — The value of the natural logarithm of 2 (log_e 2).
- `math.LOG10E` — The value of the logarithm to base 10 of `math.E` (log_10 e).
- `math.LOG2E` — The value of the logarithm to base 2 of `math.E` (log_2 e).
- `math.NAN` — A value that is "not a number." When converted to a STRING value, this is rendered as `NaN`.
- `math.NEG_HUGE_VAL` — Negative overflow value.
- `math.NEG_INFINITY` — A value representing negative infinity (−∞).
- `math.PHI` — The golden ratio (Φ).
- `math.PI_2` — The value of `math.PI` divided by two (Pi/2).
- `math.PI_4` — The value of `math.PI` divided by four (Pi/4).
- `math.PI` — The value of the ratio of a circle's circumference to its diameter (Pi).
- `math.POS_HUGE_VAL` — Positive overflow value.
- `math.POS_INFINITY` — A value representing positive infinity (+∞).
- `math.SQRT1_2` — The value of the reciprocal of the square root of two (1/sqrt(2)).
- `math.SQRT2` — The value of the square root of two (sqrt(2)).
- `math.TAU` — The value of `math.PI` multiplied by two (Tau).

### Miscellaneous

Fastly has added several miscellaneous features to Varnish that don’t easily fit into specific categories.

- `bereq.url.basename` — Same as `req.url.basename`, except for use between Fastly and your origin servers.
- **bereq.url.dirname** — Same as `req.url.dirname`, except for use between Fastly and your origin servers.
- **bereq.urlqs** — The query string portion of `bereq.url`.
- **bereq.url** — The URL sent to the backend.
- **beresp.backend.ip** — The IP of the backend this response was fetched from (backported from Varnish 3).
- **beresp.backend.name** — The name of the backend this response was fetched from (backported from Varnish 3).
- **beresp.backend.port** — The port of the backend this response was fetched from (backported from Varnish 3).
- **beresp.grace** — Defines how long an object can remain overdue and still have Varnish consider it for grace mode.
- **beresp.hipaa** — Specifies that content not be cached in non-volatile memory to help customers meet HIPAA security requirements.
- **beresp.pci** — Specifies that content be cached in a manner that satisfies PCI DSS requirements.
- **client.ip** — The IP address of the client making the request.
- **client.port** — Returns the remote client port.
- **client.requests** — Tracks the number of requests received by Varnish over a persistent connection.
- **client.socket.pace** — Ceiling rate in kilobytes per second for bytes sent to the client.
- **fastly.error** — Contains the error code raised by the last function, otherwise not set.
- **req.backend.healthy** — Whether or not this backend, or recursively any of the backends under this director, is considered healthy.
- **req.backend.is_cluster** — True if this backend, or recursively any of the backends under this director, is a cluster backend.
- **req.backend.is_origin** — True if this backend, or recursively any of the backends under this director, is not a shield backend.
- **req.backend.is_shield** — True if this backend, or recursively any of the backends under this director, is a shield backend.
- **req.backend** — The backend to use to service the request.
- **req.body.base64** — Same as `req.body`, except the request body is encoded in Base64, which handles null characters and allows rep bodies.
- **req.body** — The request body.
- **req.grace** — Defines how long an object can remain overdue and still have Varnish consider it for grace mode.
- **req.http.host** — The full host name, without the path or query parameters.
- **req.is_ipv6** — Indicates whether the request was made using IPv6 or not.
- **req.restarts** — Counts the number of times the VCL has been restarted.
- **req.url.basename** — The file name specified in a URL.
- **req.urldirname** — The directories specified in a URL.
- **req.url.ext** — The file extension specified in a URL.
- **req.restarts** — Counts the number of times the VCL has been restarted.
- **req.url.path** — The full path, without any query parameters.
- **req.urlqs** — The query string portion of `req.url`.
- **req.url** — The full path, including query parameters.
- **stale.exists** — Specifies if a given object has stale content in cache.

### Segmented Caching

Variables related to controlling range requests via Segmented Caching.

- **fastly.segmented_caching.autopurged** — Whether an inconsistency encountered during Segmented Caching processing led to the system enqueuing a purge request.
- **fastly.segmented_caching.block_number** — A zero-based counter identifying the file fragment being processed.
- **fastly.segmented_caching.cancelled** — Whether Segmented Caching processing was enabled and cancelled by a non-206 response.
- **fastly.segmented_caching.client_req.is_open_ended** — Whether the client’s request leaves the upper bound of the range open.
- **fastly.segmented_caching.client_req.is_range** — Whether the client’s request is a range request.
- **fastly.segmented_caching.client_req.range_high** — The upper bound of the client’s requested range.
- **fastly.segmented_caching.client_req.range_low** — The lower bound of the client’s requested range.
- **fastly.segmented_caching.completed** — Whether Segmented Caching processing was enabled and cancelled by a non-206 response.
- **fastly.segmented_caching.error** — The reason why Segmented Caching processing failed.
- **fastly.segmented_caching.failed** — Whether Segmented Caching processing was enabled and ended in a failure.
- **fastly.segmented_caching.is_inner_req** — Whether VCL is running in the context of a sub-request that is retrieving a fragment of a file.
- `fastly.segmented_caching.is_outer_req` — Whether VCL is running in the context of a request that is assembling file fragments into a response.
- `fastly.segmented_caching.obj.complete_length` — The size of the whole file in bytes.
- `fastly.segmented_caching.rounded_req.range_high` — The upper bound of the rounded block being processed.
- `fastly.segmented_caching.rounded_req.range_low` — The lower bound of the rounded block being processed.
- `fastly.segmented_caching.total_blocks` — The number of fragments needed for assembling this response.

## Server

Variables relating to the server receiving the request.

- `server.datacenter` — A code representing one of Fastly’s POP locations.
- `server.hostname` — Hostname of the server (e.g., `cache-jfk1034`).
- `server.identity` — Same as `server.hostname` but also explicitly includes the datacenter name (e.g., `cache-jfk1034-JFK`).
- `server.region` — A code representing the general region of the world in which the POP location resides.

## Size

To allow better reporting, Fastly has added several variables to VCL to give more insight into what happened in a request.

- `bereq.body_bytes_written` — Total body bytes written to a backend.
- `bereq.header_bytes_written` — Total header bytes written to a backend.
- `req.body_bytes_read` — Total body bytes read from the client generating the request.
- `req.header_bytes_read` — Total header bytes read from the client generating the request.
- `req.bytes_read` — Total bytes read from the client generating the request.
- `resp.body_bytes_written` — Body bytes to send to the client in the response.
- `resp.header_bytes_written` — How many bytes were written for the header of a response.
- `resp.bytes_written` — Total bytes to send to the client in the response.
- `resp.completed` — Whether the response completed successfully or not.

## TLS and HTTP/2

Fastly has added several variables that expose information about the TLS and HTTP/2 attributes of a request.

- `fastly_info.h2.is_push` — Whether or not this request was a server-initiated request generated to create an HTTP/2 Server-pushed response.
- `fastly_info.h2.stream_id` — If the request was made over HTTP/2, the underlying HTTP/2 stream ID.
- `fastly_info.is_h2` — Whether or not the request was made using http2.
- `tls.client.cipher` — The cipher suite used to secure the client TLS connection.
- `tls.client.ciphers_list_sha` — A SHA-1 digest of the raw buffer containing the list of supported ciphers, represented in Base64.
- `tls.client.ciphers_list_txt` — The list of ciphers supported by the client, rendered as text, in a colon-separated list.
- `tls.client.ciphers_list` — The list of ciphers supported by the client, as sent over the network, hex encoded.
- `tls.client.ciphers_sha` — A SHA-1 of the cipher suite identifiers sent from the client as part of the TLS handshake, represented in Base64.
- `tls.client.protocol` — The TLS protocol version this connection is speaking over.
- `tls.client.servername` — The Server Name Indication (SNI) the client sent in the `ClientHello` TLS record.
- `tls.client.tlsexts_list_sha` — A SHA-1 digest of the TLS extensions supported by the client as little-endian, 16-bit integers, represented in Base64.
- `tls.client.tlsexts_list_txt` — The list of TLS extensions supported by the client as little-endian, 16-bit, unsigned integers, represented as text in a colon-separated list.
- `tls.client.tlsexts_list` — The list of TLS extensions supported by the client as little-endian, 16-bit, unsigned integers, hex encoded.
- `tls.client.tlsexts_sha` — A SHA-1 of the TLS extension identifiers sent from the client as part of the TLS handshake, represented in Base64.

## Local variables

Fastly VCL supports variables for storing temporary values during request processing.

⭐ **TIP:** Consider using a `req.http.*` header to store a value if you need to pass information between functions or to the origin.

## Declaring a variable
Variables must be declared before they are used, usually at the beginning of a function before any statements. They can only be used in the are declared. Fastly VCL does not provide block scope. Declarations apply to an entire function’s scope even if a variable is declared within

Variables start with `var.` and their names consist of characters in the set `[A-Za-z0-9._-]`. `{;` is explicitly disallowed.) The declaration syntax is:

```
declare local var.<name> <type>;
```

### Variables types

Variables can be of the following types:

- **BOOL**
- **FLOAT**
- **INTEGER**
- **IP**
- **RTIME** (relative time)
- **STRING**
- **TIME** (absolute time)

Declared variables are initialized to the zero value of the type:

- `0` for numeric types
- `false` for **BOOL**
- `NULL` for **STRING**

### Usage

#### Boolean variables

Boolean assignments support boolean variables on the right-hand side as well as **BOOL**-returning functions, conditional expressions, and their constants.

```plaintext
# BOOL assignment with RHS variable
set var.bool = true;
set req.esi = var.bool;
set resp.http.Bool = if(req.esi, "y", "n");

# BOOL assignment with RHS function
set var.bool = http_status_matches(resp.status, "200,304");
```

#### Numeric variables

Numeric assignment and comparison support numeric variables (anything except **STRING** or **BOOL**) on the right-hand side, including conversion between **FLOAT** and **INTEGER** types, rounding to the nearest integer in the **FLOAT** to **INTEGER** case.

Invalid conditions or domain errors like division by 0 will set `fastly.error`.

```plaintext
# Numeric assignment with RHS variable and implicit string conversion for header
set var.integer = req.bytes_read;
set var(integer) = req.body_bytes_read;
set resp.http.VarInteger = var.integer;

# Numeric comparison with RHS variable
set resp.http.VarIntegerOK = if(req.header_bytes_read == var.integer, "y", "n");
```

#### String variables

String assignments support string concatenation on the right-hand side.
### IP address variables

IP address variables represent individual IP addresses.

```vcl
1 acl office_ip_ranges {
2   "192.0.2.0/24";  # internal office
3   "198.51.100.4";  # remote VPN office
4   "2001:db8:ffff:ffff:ffff:ffff:ffff:ffff";  # ipv6 address remote
5 }
6
declare local var.ip1 IP;
7 set var.ip1 = "192.0.2.0";
8
dacl 10 if (var.ip1 ~ office_ip_ranges) {
9   ...
10 }
11
declare local var.ip2 IP;
```

### Time variables

Time variables support both relative and absolute times.

```vcl
1 declare local var.time TIME;
2 declare local var.rtime RTIME;
3
declare 4 set req.grace = 72s;
5 set var.rtime = req.grace;
6 set resp.http.VarRTime = var.rtime;
7
declare 8 set var.time = std.time("Fri, 10 Jun 2016 00:02:12 GMT", now);
9 set var.time -= var.rtime;
10 # implicit string conversion for header
11 set resp.http.VarTime = var.time;
```

## Operators

Fastly VCL provides various arithmetic and conditional operators. Operators are syntactic items which evaluate to a value. Syntax is given in following conventions:

- **[ ... ]** - Square brackets enclose an optional item
- **"..."** - Literal spellings (typically punctuation) are indicated in quotes
- **CNUM** - Lexical terminals are given in uppercase
- **INTEGER** - Types are also given in uppercase
- **numeric-expr** - Grammatical productions are given in lowercase

Where a binary operator is provided, not all types are implemented on either side. This is a limitation of the current implementation. The following grammatical clauses are used in this document to indicate which types are valid operands. These are not precisely defined until the grammar is specified, and are intended as a guide for operator context only.

- **variable** - A variable name
- **acl** - An ACL name
- **expr** - An expression of any type
- **numeric-expr** - An expression evaluating to INTEGER, FLOAT, RTIME, or another numeric type
- **time-expr** - An expression evaluating to TIME
- **assignment-expr** - An expression suitable for assignment to a variable by ```set```
- **conditional-expr** - An expression evaluating to BOOL suitable for use with ```if``` conditions
- **string-expr** - An expression evaluating to STRING
- **CNUM** - An INTEGER literal
Operator precedence

Operator precedence defines the order of operations when evaluating an expression. Higher precedence operators are evaluated before the lower precedence ones. Operators are listed in the following table as the highest precedence first. For example, `a || b & & c` reads as `a || (b & & c)` because `& &` has lower precedence than `||`

Operator associativity determines which side binds first for multiple instances of the same operator at equal precedence. For example, `a & & b & & c` because `& &` has left to right associativity.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Name</th>
<th>Associativity</th>
</tr>
</thead>
<tbody>
<tr>
<td>( )</td>
<td>Grouping for precedence</td>
<td>left to right</td>
</tr>
<tr>
<td>!</td>
<td>Boolean NOT</td>
<td>right to left</td>
</tr>
<tr>
<td>&amp; &amp;</td>
<td>Boolean AND</td>
<td>left to right</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Boolean OR</td>
</tr>
</tbody>
</table>

Negation

Negation may be negated by prefixing the unary operator. This operator may only be applied to literals, and not to numeric values itself.

1 := [ "-" ] CNUM
2 | [ "-" ] CNUM ." [ CNUM ]

String concatenation

Adjacent strings are concatenated implicitly, but may also be concatenated explicitly by the `+` operator:

1 := string-expr string-expr
2 | string-expr "+" _string-expr

For example, "abc" "def" is equivalent to "abcdef".

Assignment and arithmetic operators

The `set` syntax is the only situation in which these operators may be used. Since the operator may only occur once in a `set` statement, the exclusive, so precedence between them is nonsensical.

The values the operators produce are used for assignment only. The `set` statement assigns this value to a variable, but does not itself evaluate.

FLOAT arithmetic has special cases for operands which are NaN: Arithmetic operators evaluate to NaN when either operand is NaN.

FLOAT arithmetic has special cases for operands which are floating point infinities: In general all arithmetic operations evaluate to positive or negative infinity. However some situations evaluate to NaN instead. Some of these situations are domain errors, in which case `fastly.error` is thrown accordingly. Others situations are not domain errors: ∞ − ∞ and 0 × ∞. These evaluate to NaN but do not set `fastly.error`.

Assignment

Assignment is provided by the `=` operator:

1 := "set" variable "=" assignment-expr ";"

Addition and subtraction

Addition and subtraction are provided by the `+=` and `-=` operators respectively:

1 := "set" variable "+=" assignment-expr ";"
2 | "set" variable "-=" assignment-expr ";"

Multiplication, division and modulus

Multiplication, division and modulus are provided by the `*=` and `/=` operators respectively:

1 := "set" variable "*=" assignment-expr ";"
2 | "set" variable "/=" assignment-expr ";"
3 | "set" variable "%=" assignment-expr ";"

Bitwise operators

Bitwise operators are provided by the `|=` and `&=` operators respectively:

1 := "set" variable "|=" assignment-expr ";"
2 | "set" variable "&=" assignment-expr ";"
3 | "set" variable "<<=" assignment-expr ";"
4 | "set" variable ">>=" assignment-expr ";"
5 | "set" variable "ror=" assignment-expr ";"
6 | "set" variable "rol=" assignment-expr ";"
Right shifts sign-extend negative numbers. For example, \(-32 >> 5\) gives \(-1\).
Shift and rotate operations with negative shift widths perform the operation in the opposite direction. For example, \(32 << -5\) gives 1. For right width of \(INTEGER\), shifts will yield zero or \(-1\) and rotates will use the operand modulo the width of \(INTEGER\).

### Logical operators

Logical AND and OR operators are provided by the `&&` and `||` operators respectively:

```plaintext
1 ::= "set" variable "&&=" assignment-expr ";"
2 | "set" variable "||=" assignment-expr ";"
```

These are short-circuit operators; see below.

### Conditional operators

Conditional operators produce BOOL values, suitable for use in `if` statement conditions.

#### Logical operators

Conditional expressions may be inverted by prefixing the `!` operator:

```plaintext
1 ::= "!" conditional-expr
```

Boolean AND and OR operators (`&&` and `||` respectively) are defined for conditional expressions:

```plaintext
1 ::= conditional-expr "&&" conditional-expr
2 | conditional-expr "||" conditional-expr
```

These boolean operators have short-circuit evaluation, whereby the right-hand operand is only evaluated when necessary in order to compute example, given `a && b` when the left-hand operand is false, the resulting value will always be false, regardless of the value of the right-hand situation, the right-hand operand will not be evaluated. This can be seen when the right-hand operand has a visible side effect, such as a call performs some action.

#### Comparison operators

FLOAT comparisons have special cases for operands which are NaN: The `!=` operator always evaluates to true when either operand is NaN operators always evaluate to false when either operand is NaN. For example, if a given variable is NaN, that variable will compare unequal to `var.nan` and `var.nan >= var.nan` will be false.

STRING comparisons have special cases for operands which are not set (as opposed to empty): The `!` and `!~` operators always evaluate operand is not set. All other conditional operators always evaluate to false when either operand is not set. For example, if a given variable is compare unequal to itself: both `req.http.unset == req.http.unset` and `req.http.unset ~ ".?"` will be false.

Floating point infinities are signed, and compare as beyond the maximum and minimum values for FLOAT types, such that for any finite value.

The comparison operators are:

```plaintext
1 lg-op ::= ">" | "<" | "<=" | ">="
2 eq-op ::= "==" | "!="
3 re-op ::= "~" | "!~"
```

Equality is defined for all types:

```plaintext
1 ::= expr eq-op expr
```

Inequalities are defined for numeric types and TIME:

```plaintext
1 ::= numeric-expr lg-op numeric-expr
2 | time-expr lg-op time-expr
```

Note that as there are currently no numeric expressions in general; these operators are limited to use with specific operands. For example, `2 < 5` is not.

Regular expression conditional operators are defined for STRING types and ACLs only:

```plaintext
1 ::= string-expr re-op STRING
2 | acl re-op STRING
```

The right-hand operand must be a literal string (regular expressions cannot be constructed dynamically).

### Reserved punctuation

Punctuation appears in various syntactic roles which are not operators (that is, they do not produce a value).

<table>
<thead>
<tr>
<th>Punctuation</th>
<th>Example Uses</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>{}</code></td>
<td>Block syntax</td>
</tr>
</tbody>
</table>
### Punctuation

<table>
<thead>
<tr>
<th>Example Uses</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stats ranges</td>
</tr>
<tr>
<td>Syntax around if conditions, function argument lists</td>
</tr>
<tr>
<td>Netmasks for ACLs</td>
</tr>
<tr>
<td>Separator for function arguments</td>
</tr>
<tr>
<td>Separator for statements and various other syntactic things</td>
</tr>
<tr>
<td>Invert ACL entry</td>
</tr>
<tr>
<td>To prefix fields in backend declarations</td>
</tr>
<tr>
<td>Port numbers for backend declarations, and used in the stats syntax</td>
</tr>
</tbody>
</table>

The following lexical tokens are reserved, but not used: `* | & | >> | << | ++ | -- | %`

### Types

VCL is a statically typed language. Several types are available.

#### Types for scalar values

These types are provided for scalar values, and may be assigned values from literals. Some types have units; others are unitless. These types all have implicit conversions to strings, such that their values may be used in contexts where a STRING value is necessary. The conversion is not described except for types where it differs from the corresponding literal syntax.

- **BOOL**
- **FLOAT**
- **INTEGER**
- **IP**
- **RTIME**
- **STRING**
- **TIME**

#### Types with special semantics

These types serve as points of abstraction, where internal mechanisms are separated from their interfaces to the VCL syntax. This is either defined in VCL, or provided for special cases for operations internally.

- **BACKEND**
- **HASH**
- **HEADER**
- **VOID**

### Directors

Fastly’s directors contain a list of backends to direct requests to. Traffic is distributed according to the specific director policy. Healthcheck probes should be defined for backends within directors so the director can check the backend health state before sending a request. Directors can also be used to send traffic to a backend that is identified as unhealthy.

#### Random director

The random director selects a backend randomly from the healthy subset of backends.

Each backend has a `.weight` attribute that indicates the weighted probability of the director selecting the backend.

The random director has the following properties:

- **retries**: The number of times the director will try to find a healthy backend or connect to the randomly chosen backend if the first choice is not available. If the `retries` attribute is not specified, then the director will use the number of backend members as the retry limit.
• `quorum`: The percentage threshold that must be reached by the cumulative `.weight` of all healthy backends in order for the director to consider the director healthy. If `quorum` is not specified, the director will use 0 as the quorum weight threshold.

In the following example, the random director will randomly select a backend with equal probability. At minimum, two backends must be healthy (~66%) to exceed the 50% quorum weight and qualify the director as healthy. If only one backend is healthy and the quorum weight threshold is not reached, the `error` will be returned to the client. If the random director fails to connect to the chosen backend, it will retry randomly six times before indicating all backends are unhealthy.

```vcl
1 director my_dir random {
2   .quorum = 50%;
3   .retries = 3;
4   { .backend = F_backend1; .weight = 1; }
5   { .backend = F_backend2; .weight = 1; }
6   { .backend = F_backend3; .weight = 1; }
7 }
```

### Round-robin director

The round-robin director will send requests in a round-robin fashion to each healthy backend in its backend list.

In the following example, the round-robin director will send its first request to `F_backend1`, second request to `F_backend2`, third request to `F_backend3`, and so on.

```vcl
1 director my_dir round-robin {
2   { .backend = F_backend1; }
3   { .backend = F_backend2; }
4   { .backend = F_backend3; }
5 }
```

### Fallback director

The fallback director always selects the first healthy backend in its backend list to send requests to.

In the following example, the fallback director will send all requests to `F_backend1` until its health status is unhealthy. If `F_backend1` becomes unhealthy, the fallback director will send all requests to `F_backend2` until `F_backend1` is healthy again. If `F_backend1` and `F_backend2` both become unhealthy, the fallback director will send all requests to `F_backend3` until either one of the previous backends becomes healthy again.

```vcl
1 director my_dir fallback {
2   { .backend = F_backend1; }
3   { .backend = F_backend2; }
4   { .backend = F_backend3; }
5 }
```

#### Rounding modes

Fastly VCL provides access to various rounding modes by way of independent functions for rounding values. These functions have explicit stateful interface to set a “current” rounding mode.

Fastly VCL does not provide interfaces to round values to a given number of significant figures, to a given multiple, or to a given power.

### Tie-breaking when rounding to nearest

The roundoff errors introduced by rounding values to their nearest integers are symmetric, except for treatment of the exact midpoint between two nearest integers. That is, for every value that gets rounded up (such as 3.77 rounding up to the nearest integer 4.0), there is a corresponding value (3.23) which gets rounded down the same amount. This can be seen visually:

```
<table>
<thead>
<tr>
<th>Nearest integer is 3.0</th>
<th>Nearest integer is 4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.23  3.24  3.25</td>
<td>3.5  3.75  3.76  3.77</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Rounding to the nearest integer requires a tie-breaking rule for when the fractional part of a value is exactly 0.5. There are several ways to break ties in the "to nearest" rounding modes below.

### Overview

Example values:

<table>
<thead>
<tr>
<th>Input</th>
<th>ceil</th>
<th>floor</th>
<th>trunc</th>
<th>round</th>
<th>roundeven</th>
<th>roundhalfup</th>
<th>roundhalfdown</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1.8</td>
<td>-1.0</td>
<td>-2.0</td>
<td>-1.0</td>
<td>-2.0</td>
<td>-2.0</td>
<td>-2.0</td>
<td>-2.0</td>
</tr>
<tr>
<td>Input</td>
<td>ceil</td>
<td>floor</td>
<td>trunc</td>
<td>round</td>
<td>roundeven</td>
<td>roundhalfup</td>
<td>roundhalfdown</td>
</tr>
<tr>
<td>-------</td>
<td>------</td>
<td>-------</td>
<td>-------</td>
<td>-------</td>
<td>-----------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>-1.5</td>
<td>-1.0</td>
<td>-2.0</td>
<td>-1.0</td>
<td>-2.0</td>
<td>-1.0</td>
<td>-2.0</td>
<td></td>
</tr>
<tr>
<td>-1.2</td>
<td>-1.0</td>
<td>-2.0</td>
<td>-1.0</td>
<td>-1.0</td>
<td>-1.0</td>
<td>-1.0</td>
<td></td>
</tr>
<tr>
<td>-0.5</td>
<td>-0.0</td>
<td>-1.0</td>
<td>-0.0</td>
<td>-1.0</td>
<td>-0.0</td>
<td>-1.0</td>
<td></td>
</tr>
<tr>
<td>0.5</td>
<td>1.0</td>
<td>0.0</td>
<td>0.0</td>
<td>1.0</td>
<td>1.0</td>
<td>0.0</td>
<td></td>
</tr>
<tr>
<td>1.2</td>
<td>2.0</td>
<td>1.0</td>
<td>1.0</td>
<td>1.0</td>
<td>1.0</td>
<td>1.0</td>
<td></td>
</tr>
<tr>
<td>1.5</td>
<td>2.0</td>
<td>1.0</td>
<td>2.0</td>
<td>2.0</td>
<td>2.0</td>
<td>1.0</td>
<td></td>
</tr>
<tr>
<td>1.8</td>
<td>2.0</td>
<td>1.0</td>
<td>2.0</td>
<td>2.0</td>
<td>2.0</td>
<td>2.0</td>
<td></td>
</tr>
</tbody>
</table>

A visual representation of the same:

```
<table>
<thead>

</tr>
</tbody>
</table>
```

"Direct" rounding modes

- **Round up** — `math.ceil()`
  
  Also known as ceiling, round towards positive infinity
  
  IEEE 754 roundTowardPositive
  
  Non-integer values are rounded up towards +∞. Negative results thus round toward zero.

- **Round down** — `math.floor()`
  
  Also known as floor, round towards negative infinity
  
  IEEE 754 roundTowardNegative
  
  Non-integer values are rounded down towards -∞. Negative results thus round away from zero.

- **Round towards zero** — `math.trunc()`
  
  Also known as truncation, round away from infinity
  
  IEEE 754 roundTowardZero
  
  Rounding is performed by removing the fractional part of a number, leaving the integral part unchanged.

  **NOTE:** The `FLOAT` to `INTEGER` type conversion in Fastly VCL is not by truncation (as it is in many comparable languages). See `math.round()` for rounding away from zero.

- **Round away from zero**
  
  Also known as round towards infinity
  
  Positive non-integer values are rounded up towards positive infinity. Negative non-integer values are rounded down towards negative infinity.
  
  Not provided in Fastly VCL.

"To nearest" rounding modes

All of the following modes round non-tie values to their nearest integer. These modes differ only in their treatment of ties.

- **Round to nearest, ties away from zero** — `math.round()`
  
  Also known as commercial rounding
  
  IEEE 754 roundTiesToAway
  
  For positive values, ties are rounded up towards positive infinity. For negative values, ties are rounded down towards negative infinity.
  
  This is symmetric behavior, avoiding bias to either positive or negative values. However, this mode does introduce bias away from zero.
  
  This rounding mode is used for implicit `FLOAT` to `INTEGER` type conversions in VCL. These behave as if by a call to `math.round()`.

- **Round to nearest, ties to even** — `math.roundeven()`
Also known as half to even, convergent rounding, statistician’s rounding, Dutch rounding, Gaussian rounding, odd–even rounding, and IEEE 754 roundTiesToEven

Of the two nearest integer values, ties are rounded either up or down to whichever value is even.

This rounding mode increases the probability of even numbers relative to odd numbers, but avoids bias to either positive or negative values towards or away from zero. The cumulative error is minimized when summing rounded values, especially when the values are predominantly negative.

- **Round to nearest, ties towards positive infinity** — `math.roundhalfup()`
  Also known as half up
  This is asymmetric behavior, where ties for negative values are rounded towards zero, and ties for positive values are rounded away from zero.

  ⚠️ **WARNING:** Some languages use the term half up to mean symmetric behavior. For rounding functions in these languages, "up" means towards zero, which differs from the behavior in VCL. Take care when porting a rounding mode to VCL.

- **Round to nearest, ties towards negative infinity** — `math.roundhalfdown()`
  Also known as half down
  This is asymmetric behavior, where ties for negative values are rounded away from zero, and ties for positive values are rounded towards zero.

  ⚠️ **WARNING:** Some languages use the term half down to mean symmetric behavior. For rounding functions in these languages, "down" means away from zero, which differs from the behavior in VCL. Take care when porting a rounding mode to VCL.

- **Round to nearest** with other tie-breaking schemes
  There are several other less common arrangements for tie-breaking. These include ties to odd (in a similar manner as ties to even), random or stochastic tie-breaking.

  These schemes are not provided in Fastly VCL.

Floating point numbers have more computational nuances than are described by the cursory discussion of biases here. For more details, see the scientist should know about floating-point arithmetic.
